Recommended for the many patients who are too nervous or agitated to be adequately calmed by sedatives or weaker tranquilizers Serpasil actually sets up a "stress barrier" against anxiety and tension these patients would otherwise find intolerable *Average Dose* 0 1 mg to 0 5 mg (two 0 25-mg tablets) daily

Although it is a first choice in hypertension, Serpasil does not significantly lower blood pressure in normotensive patients

SUPPLIED:
Tablets, 0 1 mg 0.25 mg 1 mg 2 mg and 4 mg
Elixirs, 0.2 mg and 1 mg per 4-ml teaspoon
Parenteral Solution: *Ampuls, 2 ml, 2.5 mg Serpasil per ml*
Multiple-dose Vials 10 ml 2.5 mg Serpasil per ml

pertension and emotional disorders

Serpasil®

MAGAZINE—TELEVISION REPORT

The following list of current medical articles in mass circulation magazines on medical subjects is published each week only for the information of readers of The Journal *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles reported*

MAGAZINES

Sports Illustrated, Aug 5, 1957

A Measure of Fitness by Dorothy Stull

Minimum requirements for school physical education programs are being threatened by the continuous rapid suburban expansion outward from the great metropolitan centers In some cases the suburbs have grown so fast that the powers that be and the citizens groups are not worried about proper physical education facilities, they are worried about whether they will have a school at all

The American Weekly, Aug 18, 1957

How We'll Fight the Asiatic Flu by William Engle

The article reassures readers about the impending flu epidemic You will probably be ordered to bed for from 24 to 48 hours Aspirin and codeine may ease your discomfort and alcohol rubs and ice packs will help reduce your fever If you develop no complications you'll be none the worse for the tussle

The Atlantic Monthly, August, 1957

Fall-out Fever, by Ernest C Pollard Ph D

In a thorough discussion of the H-bomb fall out problem Dr Pollard, chairman of the biophysics department at Yale University, observes All that will be seen by some people is that we may make a case that weapons testing will result in the unnecessary death of twelve people in the United States per year due to leukemia These are twelve unnecessary deaths in perhaps 10,000 leukemia deaths, but they are twelve Are we to say that this is a hateful thing akin to murder, or are we to say that such deaths are simply a necessary sacrifice for our defense, which we as a sturdy race will take in our stride, and so will develop into a tougher future generation? Again the moral lines are hard to draw

The American Mercury, August, 1957

'Poison in Your Water, by Leo Spira, M D

In an article setting forth dangers of adding fluorine to drinking water, the author writes Since fluorine is already present in our average normal food in quantities sufficient to produce chronic illness, it is obvious that any increase in the fluorine content is certain to be dangerous

Lobotomy Is a Dangerous Weapon, by Stephanie Williams

The article questions the wisdom of state and national mental health legislation which the author believes may open the way to use of mental health institutions and lobotomies as political weapons in the hands of the unscrupulous

Why Are You Nervous? by Robert J Needles, M D

'If man is not allowed to decide for himself how he is to live, he will not escape anxiety in his grave

Germs Can Get Sick Too' by Irving J Weiss

The author discusses phage and speculates that scientists may someday be able to use phage to protect mankind from bacteria

The Saturday Evening Post, Aug 10, 1957

Don't Let Medical Bills Bankrupt You,' by E R Leibert

The author tells of how his daughter's illness put a financial burden on his family He advises major medical health insurance for all families, and describes the types of policies available

PREOPERATIVE SEDATION AND PRODUCTION OF A QUIESCENT STATE IN CHILDREN

PROMETHAZINE-MEPERIDINE-SCOPOLAMINE SEDATION

Max S. Sadove, M.D.
and
Theodore J. Frye, M.D., Chicago

• Previous experience with 3,000 surgical cases showed that meperidine and promethazine together were an extremely satisfactory combination for use as premedication for anesthesia. A method for administering them was evolved from this experience and was applied uniformly in a special series of 200 consecutive pediatric cases. Promethazine, 1.1 mg per kilogram of body weight (0.5 mg per pound), was injected intramuscularly 60 to 90 minutes before induction of anesthesia, meperidine in the same dosage was given intramuscularly 30 to 60 minutes before induction. Scopolamine in doses ranging from 0.1 to 0.43 mg (1/650 to 1/150 grains) according to the body weight was given with the meperidine. This premedication sufficed to eliminate all signs of dread in 93% of the children, suppressed motor activity in 92%, induced sound sleep in 12%, and eliminated all reactions to the environment in 80%. The over all effect, in the opinion of the anesthesiologist, was that induction was facilitated in 80%, unaffected in 17% and delayed in 3%. There was no cyanosis or vascular depression in any case, and only one of the 200 patients vomited. Since a parallel series permitting comparison with other types of premedication remains to be completed, the authors regard this as a preliminary report.

Preoperative sedation of children is a difficult problem of great importance, for the psychic trauma consequent to anticipation of surgery may be as great a hazard to the patient as his original disease. Also, in many instances it is questionable whether the risk from preoperative sedatives, administered to relieve apprehension, may not be as great or greater than the risk from the operation itself.

The search for the ideal in preoperative sedation has been pursued for years. No method has been universally accepted, although many surgeons and anesthesiologists have favorite drug combinations that appear to work well in their hands. The drugs used depend to a considerable degree on the disease under treatment, the physical status of the patient, the operative procedure and the anesthetic technique to be employed, and other factors.

The requisites for preoperative medication of children include (1) safety, (2) simplicity (no excessive problems as to administration, timing, or equipment should attend use of the method), (3) wide applicability, (4) facilitation of anesthetization, and (5) adequate quieting action. Ideally, the child should arrive in the operating room without apprehension or fear, a degree of hypnosis or sleep is desirable, without, however, any depression of vital functions, especially those of circulation and respiration.

The method should be free of untoward effects, such as occasional overdepression or, at the other extreme, inadequacy of sedative action, nausea, vomiting, and constipation. Definite predictability of effect is necessary, so that the percentage of failures per unit number of cases will be minimal.

In the past the entire range of drugs of a sedative type have been used for premedication in children. With the exception of potent narcotic agents, all have been tried and found useful in some cases but not satisfactory for a large percentage of children. Bromides, chloral hydrate, and paraldehyde have been used by many but have failed to approximate the ideal in preoperative sedation.

The avenues of administration employed have included the oral, the intramuscular, the intravenous, and the rectal. Medication by the oral route may be suitable for sedation in other branches of medicine, but it increases the hazard of regurgitation or vomiting

---

From the Department of Surgery, Division of Anesthesiology, University of Illinois Research and Educational Hospitals.

if used in the preoperative period In a frightened child, absorption of a medicament from the intestine may be slow

The sedatives most commonly employed today are the barbiturates of ultrashort, short, and intermediate duration of action, supplied in the form of capsules, suppositories, and solutions and suspensions administered parenterally or by rectum The ultra-short-acting or the short-acting barbiturates, administered rectally, have proved useful However, with medication by the rectal route there is always the possibility that the drug may be expelled or may not be absorbed or that absorption will be prolonged beyond the period when sedation is required Side-actions, such as slight to severe depression of circulation or respiration or both, have occurred, as well as long-continued somnolence in the postoperative period, and have been definite deterrents The problems of rectal administration in many instances are so troublesome as to render such methods impractical

ANESTHESIOLOGIST

Work sheet in preoperative sedation of children with combination of promethazine, meperidine, and scopolamine

Intramuscular or oral administration of various barbiturate compounds has become rather popular in recent years However, it is difficult to ascertain the correct dose of barbiturate for a particular child to provide a predictable degree of sedation It has become common practice, therefore, to use slightly more than the conventional dosage, thus, failures are relatively few, but the incidence of excessive sedation in the postoperative period is increased

Investigation into Preanesthetic Quiescence

Background of Present Study—During an investigation of a number of phenothiazine derivatives, among them chlorpromazine, promethazine, and mepazine over the past three years, the potentiating action of these compounds on narcotics and other commonly used premedicants and on agents used to produce basal anesthesia was observed More than a year ago use of promethazine in conjunction with meperidine was initiated, and the series was extended to 3,000 cases[1] The combination proved extremely satisfactory and our confidence in the technique increased Carefully and cautiously, the study was expanded to include pediatric surgical cases With accumulation of cases we evolved a method of administering the various agents in a definite ratio to one another in relation to the body size of the patient Although records of a large number of cases were by this time available, it was felt that for purposes of accuracy another series should be started

Plan of Investigation—The present study was undertaken to evaluate the efficiency of the promethazine meperidine scopolamine combination for preoperative medication of children Two hundred consecutive cases were carefully evaluated A work sheet (see figure) similar to those used previously, was completed for each patient In this study the use of promethazine in 25 to-50 mg doses given orally the evening preceding surgery has provided adequate restful sleep and has eliminated the need of barbiturates in most cases

Dosage—All patients under 12 years of age received routine preoperative medication computed on the basis of body weight and administered without regard to physical status, operative risk or anesthetics to be used (see table) Promethazine, 0 5 mg per pound, was injected intramuscularly 60 to 90 minutes prior to induc tion, meperidine, 0 5 mg per pound, and scopolamine (see table) were administered by the intramuscular route 30 to 60 minutes prior to initiating anesthesia

Results

Results were evaluated according to the sum total of apprehension, excitability and reaction to environment of the patient and the over-all quiescence achieved Each factor in the emotional condition of the patient was appraised, since certain drug combinations may alter some factors without influencing others, yet each must be considered an integral part of the entire response to sedation The anesthesiologist was instructed to be as objective as possible in each case It was our desire not only to record the absence or the presence of the various physiological and psychological phenomena but also to evaluate the degree to which the various reactions were present The psychophysiological functions involved were therefore graded by a numerical system (see figure) Naturally, our interest was centered on the degree of preoperative sedation and quiescence attained

Apprehension—A state of fear or dread within the individual was not discernible in 93% of the patients, was slight in 4% and was severe in 3% When there are considered such factors as the type of patients comprising the series, the economic strata from which they came, and the fact that many of them were hurried into the hospital immediately prior to the time of induction, the effectiveness of the premedication for prevention or relief of apprehension was impressive

Excitement—Motor activity, especially as an expression of fear and apprehension, was absent in 92% of the patients, was slight in 4%, and was moderate to severe in 4% This drug combination may be considered very effective in preventing excitement, particularly when it is realized that most of the patients in this series were treated under clinical conditions common to a large active service in a metropolitan area, in many instances, because of the extremely heavy work load, timing of the premedication could not be ideal

Sleep Before Induction—The presence or absence of sleep prior to induction was observed (With other types of premedication, sleep is essentially synonymous with adequate sedation) In this series, less than half of the patients were asleep or in a sleep-like state on arrival in the operating room, only 12% were soundly asleep, and 30% were sleeping intermittently Thus, the majority (58%) were fully conscious but quiet and tractable immediately prior to induction

Sedation and Quiescence—Sedation and quiescence were evaluated on the basis of the sum total of all observable phenomena indicating psychomotor depression Seventy-three per cent of the patients were moderately to profoundly sedated, 22% were slightly sedated, and 5% showed no sedation In the over-all assessment of the sedative response, it was estimated that the quiescence produced was adequate in 92%

Reaction to Environment—Reaction to the operating-room environment is an excellent indication of the true sensitivity of the individual to his surroundings The quiescence of the patient was severely tested during the positioning on the table, injection of drugs, placement of the needle for intravenous injection starting of the infusion, and other necessary manipulations immediately prior to induction Under many forms of preanesthetic medication, a child may appear to be adequately sedated, yet, he may 'break through when he is manipulated in any way, as during the routine preparations in the operating room

Routine Dosage of Promethazine Meperidine and Scopolamine Computed on Basis of Body Weight

Age	Weight Lb	Promethazine Mg	Meperidine Mg	Scopolamine Grains
Up to 2 mo	7 10	3 5 5 0	3 5 5 0	1/650
2-4 mo	10-14	5 0 7 0	5 0- 7 0	1/450
4-6 mo	14 16	7 0 8 0	7 0- 8 0	1/450
6-12 mo	16 22	8 0-11 0	8 0-11 0	1/450
12 18 mo	22 25	11 0 12 5	11 0 12 5	1/400
18-24 mo	25-27	12 5 13 5	12 5-13 5	1/400
2 3 yr	27 30	13 5-15 0	13 5 15 0	1/300
3 5 yr	30-40	15 0-20 0	15 0 20 0	1/300
5-8 yr	40-55	20 0-27 5	20 0 27 5	1/150
8-10 yr	55-65	27 5-32 5	27 5 32 5	1/150
10-12 yr	65 80	32 5 40 0	32 5-40 0	1/150

In 80% of the patients in this series there was no reaction whatever to the environment Sixteen per cent were slightly disturbed, and only 4% registered a moderate to severe protest to the final preparations for operation The type of premedication used in this series, therefore, is excellent for the purpose of diminishing the reaction of the child patient to environmental stimuli

Facilitation of Anesthetization—The evaluation of the ability of this method of preoperative sedation to facilitate anesthetization was based purely on clinical impressions The phases are listed on the work sheet (see figure) under induction, maintenance, and emergence

Induction Induction was facilitated, in the opinion of the anesthesiologist, in 80% of the cases In 20% the premedication was considered not to be helpful, and in 3% of these there was an impression of actual delay in induction

Maintenance Maintenance was facilitated in 90% of the cases, and in 10% no opinion could be expressed as to the value of the premedication On evaluation of the amount of anesthetic employed in this series, it was the impression that less was required for maintenance in 62% of the cases, in 37 5% the amount required deviated in no way from the standard, and in only one case (0 5%) did the anesthesiologist feel that more of the agent was required than usual

Emergence Many undesirable side-effects from excessive preoperative sedation are seen during emergence from anesthesia, including delay in recovery, excitement, disorientation, panic, nausea, and vomiting It was to be expected that emergence, in a series of this size, would be delayed in at least a few patients and that for others there would be 'no change' or the effects would be recorded as 'unknown However, it was considered that the quiescence produced by the preoperative medication contributed to a smoother, quieter emergence in 80% of the patients, in only 20% was the method noncontributory or the effect unknown

It is believed that, because less anesthetic was required for maintenance of anesthesia in a high percentage of the patients, emergence was more rapid in these patients, with less hypoxia and other evidences of depression of vital centers than would have occurred with conventional preoperative techniques It also has been suggested that the potentiating activity of promethazine on the analgesic drug administered before operation may have been carried over into the postoperative period, so that the patient had the benefit of an additional analgesic effect and therefore a more comfortable emergence from anesthesia

Respiratory Depression —Potentiation of the depressant effects of the analgesic and anesthetic agents by promethazine was evaluated by clinical observation We were vigilant for adverse influences on the vital functions, especially when respiratory depressants were used during anesthesia In 97% of the patients no respiratory depression attributable to the premedication was clinically discernible Only 3% showed a slight to moderate respiratory depression that might have been remotely related to the preoperative medication

Vascular Depression —The children were observed for changes in peripheral pulse rate, blood pressure, capillary refill time, and other phenomena indicating alteration of the circulatory mechanism None showed any indication of vascular depression Skin color was watched with particular attentiveness, because peripheral cyanosis has occurred in adults under premedication with a phenothiazine compound but has not been seen in children None of the patients in this series became cyanotic, and in only one was the skin color in any way unsatisfactory This child, who had multiple congenital deformities and relative anemia and had had a number of previous operations, showed pallor prior to induction

Vomiting —Throughout the entire period of observation vomiting occurred in the case of only one patient (0 5%) in the immediate postoperative period This is a noteworthy finding, since a greater incidence of emesis would ordinarily be expected in a series of 200 patients The rarity of vomiting in this series certainly is an indication of the antiemetic properties of promethazine Also, an important factor in the control of emesis was the smoother maintenance of anesthesia with less amount of anesthetic, and a consequent reduction of hypoxia and vital depression Local tolerance to the intramuscular injection of promethazine was excellent There was no pain on injection and no evidence of local tissue reaction

Comment

Final Evaluation —In the final summation of the usefulness of promethazine in premedication, the anesthesiologist indicated on the work sheet his opinion as to the helpfulness or the lack of helpfulness of the compound Promethazine was considered definitely helpful in 85% of the cases, was felt not to be helpful in 2%, and in 13% no conclusion as to the over all value of the drug could be reached

Additional Observations —If sedation is inadequate, patients tend to show overactivity in the postoperative period Prior to inception of this series, it was observed in routine work of the operating room, and confirmed during this study, that, if small divided doses of approximately 0 5 mg of promethazine per pound of body weight were administered by slow intravenous injection, an excellent state of general quiescence without vital depression developed within 10 minutes The patient became cooperative, responded to the spoken word, and was easily manageable, in contrast to the previous situation

Summary and Conclusions

In a clinical evaluation of the preoperative sedation and quiescence produced by a combination of promethazine, meperidine, and scopolamine administered to 200 children in dosage determined by body weight, various psychophysiological phenomena were closely observed and tabulated The study has been based on clinical observations As such, it is fraught with the hazards common to all studies of this type It is now being expanded under more controlled conditions Our justification for publishing the study, prior to the completion of the controlled study, is our sincere belief that, although the percentage of various conclusions may change, the over-all individual conclusions will remain valid

Observations were made of the effect of promethazine-meperidine-scopolamine premedication on anesthesia and the postoperative period According to these observations, respiratory depression of a clinically discernible type was rare and mild, being present in only 3% of the patients Vascular depression was not observed Vomiting in the operative and postoperative periods was markedly diminished to the degree of being almost nonexistent The amount of anesthetic required to obtain and maintain adequate anesthesia was diminished in more than half of the cases

Inasmuch as more than 90% of the children were free from apprehension through use of the preoperative sedation, this psychic factor was practically eliminated Excitement or motor activity, especially as an expression of fear, was present in less than 10% of the patients Reaction to hospital and particularly operating-room environment (which is one of the phenomena that best measures the efficiency of pre operative medication) indicated that more than 80% of the children were excellently tranquilized. Actual sleep or sleep-like state was present in a little less than 50% of the cases. Sedation was adequate in all but 5%.

As to final evaluation, in more than three-fourths of the patients anesthetization was facilitated as to induction, maintenance, and emergence from anesthesia by means of preoperative sedation with promethazine, meperidine, and scopolamine. It was the opinion of the anesthesiologists that this drug combination was helpful in approximately four-fifths of the cases studied.

840 S. Wood St. (12).

The promethazine used in this study was supplied as Phenergan by Wyeth Laboratories, Philadelphia, the meperidine used was supplied as Demerol by Winthrop Laboratories, New York.

MICROCOCCIC (STAPHYLOCOCCIC) INFECTIONS IN A GENERAL HOSPITAL

Donald N. Wysham, M.D.
and
William M. M. Kirby, M.D., Seattle

• *Micrococcic infections resulting from cross infection within hospitals may be the most serious current communicable disease problem. Micrococci are remarkably well adapted for cross infection in a hospital environment, remaining viable and even virulent in a dried state on dust or bedding. Any break in the skin, surgical or traumatic, including that made by intravenous catheters, appears to open the way for micrococcic invasion, and in infants invasion may take place through normal, intact skin. Hospital-acquired infections seem largely preventable, and the application of control measures including isolation of hosts and sterilization of vectors must be put into effect.*

Micrococcic (staphylococcic) infections of hospitalized patients are a subject of increasing concern to the medical profession. Reports have appeared in Canadian, British, and Australian literature implicating micrococci in certain types of hospital-acquired infections, such as surgical wound infections,[1] impetigo neonatorum, and maternal breast abscesses.[2] Similar studies have been published in the United States.[3]

Though specific types of micrococcic infection have been reported, there is no current description in medical literature of the scope of the problem of such infections in a general hospital. Information is not available concerning the approximate incidence of such infections, nor is a description of the types of infections commonly encountered and their severity. Such data are valuable in order to provide perspective to the problem, to stimulate investigation of various means of control, and to permit evaluation of preventive measures. With these objectives in view, data were collected in the King County Hospital from Nov. 16, 1955, through February, 1956, and serve as the basis of this report.

Methods and Materials

All hospital patients with newly acquired micrococcic infections proved by culture were followed in this study. The principal method utilized was the investigation of every culture positive for micrococci, which was routinely isolated by the hospital laboratory, in order to determine its source, the clinical condition of the patient, the time of onset of infection, and other data. With the information thus gained, it was generally possible to determine whether the source of the culture was a clinically significant micrococcic infection or if it had been derived from some other source, such as a nasal carrier of micrococci.

Patients were included in this study only if they had definite clinical infections from which coagulase-positive micrococci were isolated in large numbers. Patients who had multiple micrococcic infections were listed only once. Such patients were classified by what appeared to be the most serious of their infections. Coagulase-negative micrococcic isolations were disregarded. Patients who had chronic micrococcic infections acquired prior to the study were not counted in tabulations, though many cultures from such patients were obtained during the study. Fifteen of these patients were investigated and are considered separately in the text.

It was found that patients with recently acquired micrococcic infections fell into one of three fairly distinct and significant groups: (1) those who acquired their infections outside the hospital and who were admitted or were seen in the outpatient department, (2) those in whom no evidence of infection was present on hospital admission but who developed infections one or more days after admission, and (3) those whose infections appeared within 60 days after discharge from the hospital. Six hospital employees who developed micrococcic skin infections are included in the group of patients whose infections appeared while in the hospital. Seven patients who apparently acquired infections in other hospitals are not listed.

During the period of the study and for approximately one month thereafter, all deaths among patients in the series were noted and reviewed in detail with a pathologist to determine the relationship, if

From the University of Washington School of Medicine, the King County Hospital, and the Washington State Department of Health, Seattle, and the Communicable Disease Center, United States Public Health Service, Department of Health, Education, and Welfare, Atlanta, Ga. Dr. Wysham is now an Assistant Resident in Medicine at the New York Hospital.

any, of the micrococcic infection to the patient's death Only those deaths in which the infection appeared to play a significant role are included in this report

The sensitivities of micrococci to antibiotics were tested by the disk diffusion technique, described elsewhere[4] Antibiotics used in determining sensitivities were tetracycline, chloramphenicol, streptomycin, *penicillin, erythromycin, and bacitracin For the pur*poses of this study, organisms moderately or markedly resistant to an antibiotic were regarded as resistant to that antibiotic

TABLE 1 —*Types of Micrococcic Infections Found Among 189 Patients from Nov 16, 1955, Through February, 1956*

* Does not include several deaths among infected patients whose death did not appear related to micrococcic infection

† Group 1 infections acquired outside hospital group 2 infections appearing during hospitalization group 3 infections appearing after discharge

Bacteriophage typing of a sample of micrococci was performed by Major George Navarre, Branch Sixth Army Area Medical Laboratories, Fort Lewis, Wash Major Navarre utilized 26 bacteriophages, the majority of which were derived from the reference strains of Dr John Blair, New York City

Results

One hundred eighty-nine patients developed micrococcic infections from which material was cultured during the period of this investigation The number of infections occurring each month was relatively constant and was in the order of 55 per month

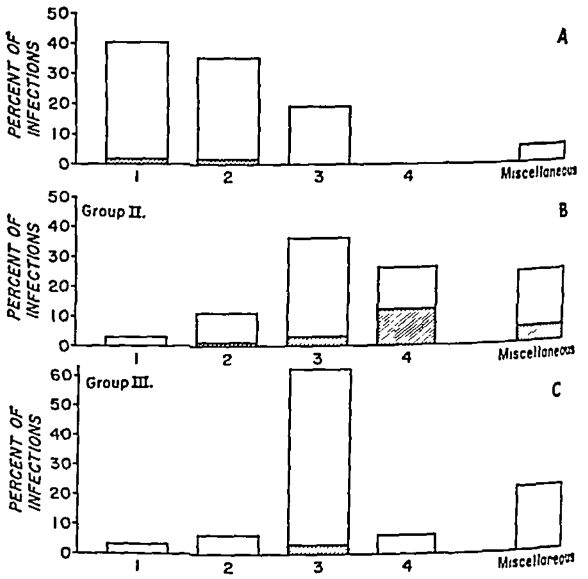
Table 1 summarizes the types of micrococcic infections in each of the above-mentioned three groups—group 1, those acquired outside the hospital, group 2, those developing during hospitalization, and group 3, those appearing after discharge

Group 1, Infections Acquired Outside Hospital—Fifty-seven infections, comprising 30% of the total, were acquired outside the hospital The majority of these were skin infections of adults, including many carbuncles and infected abrasions or lacerations treated in outpatient clinics The bulk of the remaining infections in this group, classified as miscellaneous, is comprised largely of urinary tract infections, otitis media, conjunctivitis, and lymphadenitis

Such infections acquired outside the hospital were usually not severe This is reflected by the relatively low mortality rate of about 4% Micrococcic septicemia was presumably responsible for the two deaths which occurred in the group One of the patients who died was a 77-year-old diabetic woman She had been febrile when admitted, and died two days later A Micrococcus sensitive to all antibiotics was cultured from her blood The other patient had entered with symptoms of septicemia and meningitis after a short history of severe, spiking fever, preceded by persistent carbuncles for several weeks Culture of his spinal fluid was positive for micrococci resistant only to penicillin He died on the day after admission. At autopsy, miliary micrococcic abscesses were found in several organs, including the kidneys and brain Since no positive blood culture was obtained from this patient, he is listed in the miscellaneous column in table 1

The resistance to antibiotics of infections in group 1 represents the antibiotic resistance of micrococcic infections in outpatients of the King County Hospital Forty per cent of these infections were caused by organisms sensitive to all antibiotics, and 35% were resistant only to penicillin (table 2 and the figure) Nineteen per cent were resistant to tetracycline, streptomycin, and penicillin, a pattern frequently seen in hospital-acquired infections In several instances of infections with this resistant pattern, other members of the patient's family had recently been hospitalized, thus suggesting that the hospital may have been the indirect source of some of the infections in this group

Group 2, Infections Appearing During Hospitalization—Infections appearing during hospitalization, totaling 100, made up the majority of infections encountered These micrococcic infections appeared as early as the second day of life in a newborn infant and, in the extreme case of a convalescent poliomyelitis patient, 13 months after admission For those patients for



Antibiotic sensitivity patterns of micrococcic infections *A*, Group 1 (57 infections), those acquired outside the hospital *B*, Group 2 (100 infections), those appearing during hospitalization, *C*, Group 3 (32 infections), those appearing after hospital discharge 1 stands for sensitivity to all antibiotics, 2, resistance only to penicillin, 3, resistance to tetracycline, streptomycin, penicillin, 4, sensitivity only to bacitracin, and miscellaneous, other resistance patterns The shaded areas indicate deaths.

whom the interval from admission to the onset of infection could be clearly determined, the median interval was 10 days

Twenty-six infections, a quarter of the group, were surgical wound infections Such infections most often appeared in the relatively avascular tissues of elderly patients, but infections also occurred in young and apparently healthy persons Five patients with surgical wound infections died In each of the deaths, the wound infection was a contributing factor or major cause of death

In 12 known instances, pneumonia was the major micrococcic infection The pathological picture in fatal cases was usually bilateral bronchopneumonia of the lower lobes In severe cases, the pneumonia was necrotizing and hemorrhagic, occasionally with abscess formation In several fatal cases of pneumonia with this pathological picture, material was not taken for culture at autopsy, thus these cases are not included in the statistics of this report Also, several patients dying with other micrococcic infections appeared to have micrococcic pneumonia as a terminal complication It is probable that the incidence of micrococcic pneumonia is considerably higher in this hospital than these data indicate

* See table 1 for explanation of groups

Of the 12 patients with pneumonia who are listed, eight died All of them were debilitated by degenerative diseases or by serious trauma In six instances the lung infection was preceded by cerebral injury with coma

In the entire study, 12 patients were seen with blood cultures positive for micrococci, of these, 6 died Eleven of the patients with bacteremia had micrococcic infections that appeared during hospitalization In five such instances of bacteremia, a major micrococcic infection was present, such as pneumonia or a wound abscess, which was considered the source of the disorder The condition of those patients who had positive blood cultures without an obvious source of the disorder is classified as septicemia Six of the patients with 'primary septicemia are listed in group 2, three of them died In these cases of primary septicemia, there appears to be a suggestive epidemiologic relationship to intravenous therapy All of these patients had received fluids intravenously More significantly, a femoral catheter had been used in one case, a venous "cut-down' in two, and in one continuous intravenous therapy had been given from admission until death Intravenous therapy may well provide a way for micrococci in a patient's environment to enter his blood stream

Eighteen skin infections of infants occurred during this investigation in group 2 In addition, two breast abscesses occurred in mothers and two in infants

These were a portion of a prolonged outbreak of micrococcic infections originating in the nursery Infections of infants appeared usually as pustules, infected blebs, or furuncles Nearly all of these infections in infants and mothers had identical antibiotic sensitivities, with resistance to tetracycline, streptomycin, and penicillin Several infections were severe enough to require readmission to the hospital or prolongation of the postpartum or neonatal hospitalization period by several days No deaths occurred, however, in this group

Skin infections of adults, including infected decubitus ulcers, infections of burns, and the miscellaneous group of infections, including those of the urinary tract, comprise the remainder of infections appearing in hospitalized patients Two of the adults with skin infections died, probably as a result of septicemia in both cases, though positive blood cultures were not obtained The two deaths occurring in the group with miscellaneous infections were both in patients with severe micrococcic parotitis

The severity of infections in group 2 is reflected by the mortality rate of patients in this group (tables 2 and 3) Of the 100 patients in the group, 21 died In each of these 21 deaths, the micrococcic infection played a role—a major or determining role in 15 cases The mortality rate in this group was 21%, as compared with the mortality rate of less than 4% for infections acquired outside the hospital (table 2) The over-all mortality rate in groups 2 and 3, considering only deaths related to micrococcic infection, is 17% (22 deaths out of 132 cases)

The severity and prolonged morbidity of certain micrococcic infections is also evidenced by 15 patients who had developed chronic infections prior to this study Twelve of the patients evidently had developed their infections while in this hospital These micrococcic infections had persisted for periods varying from 4 days to 4 5 years before the initiation of this study, averaging 10 5 months in duration Six of the patients, including three with postsurgical osteomyelitis, had required several months of hospitalization because of their infections Even when such patients were not hospitalized, their infections appeared to cause considerable disability and economic loss

The susceptibility to antibiotics of organisms causing infections occurring in the hospital contrasted sharply with the antibiotic sensitivity of organisms causing infections acquired outside the hospital (table 2 and the figure) The organisms causing only 3% of the infections which appeared in the hospital were sensitive to all antibiotics, and those causing 11% were resistant only to penicillin The organisms causing 36% were susceptible to chloramphenicol, erythromycin, and bacitracin and resistant to tetracycline, streptomycin, and penicillin The organisms cultured in 26% of the infections were sensitive only to bacitracin A remarkably high mortality rate of 46% (12 deaths out of 26 cases) was observed in patients with infections caused by organisms susceptible only to bacitracin

The remaining 24% of hospital-acquired infections were caused by organisms with various other patterns of antibiotic resistance Most of these were resistant to two or more antibiotics

* Outside refers to those infections acquired outside hospital Hospital to those appearing during hospitalization Postdischarge to those appearing after discharge

Group 3, Infections Appearing After Discharge—The third major group of micrococcic infections is composed of those appearing after discharge from the hospital Thirty-two patients had infections in this group Their infections became evident from 2 to 60 days after discharge Ten of these patients had infections of surgical wounds, one of them died of a wound abscess while in a convalescent hospital Skin infections of eight infants and the breast abscesses of four mothers and one infant comprise most of the remainder of the group

The antibiotic-resistance pattern of the causative organisms in this group of infections is similar to that for the infections appearing in hospitalized patients (table 2 and the figure) In only 3 of the infections (9%) was there no antibiotic resistance or resistance only to penicillin, in contrast to 43 (75%) of the infections acquired before hospital admission The remaining 91% of infections appearing after discharge were caused by organisms moderately to markedly resistant to antibiotics The majority (62%) of the organisms were sensitive only to chloramphenicol, erythromycin, and bacitracin

Bacteriophage Typing

Bacteriophage typing of a sample of cultures from micrococcic infections was utilized to investigate the possibility that one or two strains were causing the majority of infections Micrococci isolated from the infections of 58 of the patients in this series, predominantly during January, 1956, were subjected to bacteriophage typing

It is apparent from table 4 that, at least during the month of January, no single bacteriophage type was responsible for a majority of infections Forty per cent of the cultures were not typable with the bacteriophages used Twenty-four per cent, or 14 isolations of micrococci, were typed in 9 different phage patterns One of these patterns (53/54/77/VA4) appeared three times, three patterns appeared twice, and each of the other five patterns was observed only once

The remaining 36% of infections, however, were evidently caused by the same bacteriophage type of Micrococcus, type 52/42B/44A Micrococci of this bacteriophage type appear to have caused many recent outbreaks of micrococcic infections in nurseries in the United States[5] In this hospital, 8 of the 21 isolations of this bacteriophage type were cultured from material drawn from the infections in newborn infants or their mothers Thirteen strains of micrococci of this type appeared in other groups of patients, including a culture from the blood of an adult who died of micrococcic septicemia Seven of the isolations of this bacteriophage type occurred in persons who evidently acquired their infections outside the hospital

It was of interest to note the relationship of bacteriophage types to antibiotic sensitivity patterns Of the 21 cultures of bacteriophage type 52/42B/44A, 16 had the same antibiotic sensitivity pattern—resistance to tetracycline, streptomycin, and penicillin and sensitivity to chloramphenicol, erythromycin, and bacitracin Comprising half of these 16 were the 8 from infections whose source appeared to be the nursery Three micrococcic isolates of this bacteriophage type were sensitive to all antibiotics tested, and two were resistant to all antibiotics except bacitracin No other correlations were evident between antibiotic sensitivity and bacteriophage type, with the possible exception that, of nine cultures sensitive only to bacitracin, six were nontypable

Source of Infection

The source of the micrococci causing infection within the hospital is a subject of critical importance It has been suggested that those hospitalized patients who acquire micrococcic infections are normal carriers of coagulase-positive micrococci, which are harmless during normal activities but are enabled to produce clinical disease because of a change in the patient's resistance after entering the hospital, e g , through surgical incision of the skin or from the results of prolonged bed rest, such as the pooling of secretions in the lungs or pressure necrosis of cutaneous areas

However, this appears unlikely in this study, since the antibiotic-sensitivity patterns of micrococci isolated from infections acquired within the hospital were found to be strikingly different from that of micrococci causing infections acquired outside the hospital In another recent study, to be published separately, we found that none of 118 newly admitted patients were demonstrably nasal or skin carriers of micrococci resistant to antibiotics other than penicillin It would seem quite improbable that patients who developed infections in the hospital entered the hospital carrying highly resistant micrococci Thus, on the basis of this indirect evidence, one may presume that the micrococci causing infections of hospitalized patients are different from those which the patients may have carried into the hospital, differing at least in their sensitivity to antibiotics

It is reasonable to consider whether antibiotic therapy of the hospitalized patient could account for this difference by inducing antibiotic resistance in bacteria normally carried by the patient If this were true, it would be essential that antibiotic resistance develop very rapidly in order to account for the early appearance of infections due to antibiotic-resistant strains The median interval from admission to signs of infection was only 10 days in this study Also, it would be expected that the type of antibiotic resistance should bear a close correlation to antibiotics

* See table 1 for explanation of groups

the patient had received Neither of these conditions has been found to exist, either in our experience or in that of other investigators Finland[6] states that the acquisition of increased resistance to antibiotics during treatment occurs infrequently with most of the antibiotics Knight and Collins[7] found that patients became nasal carriers of micrococci with antibiotic-sensitivity patterns unrelated to antibiotics the patient had received They concluded that antibiotic therapy, by eliminating normal, antibiotic-sensitive flora, facilitated colonization of the patient's nasal mucosa by resistant micrococci which are prevalent in the hospital environment

The mechanisms of mutation and selection of antibiotic-resistant bacteria probably play a major and continuing role in the recruitment of new resistant strains to the population of hospital micrococci Neither mechanism, however, seems to play an immediate role in most hospital-acquired infections Instead, most such infections are probably the result of the transmission of antibiotic-resistant strains from patient to patient or from personnel to patient[8] Studies with bacteriophage typing of micrococci support this conclusion[6]

Micrococci are remarkably well adapted for cross-infection in a hospital environment They will evidently remain viable, and may remain virulent, in a dried state or on dust, bedding, or other fomes for months or years[9] They may reside for long periods in nasal passages of hospital personnel or patients[10] Once they succeed in producing an infection, they apparently multiply quickly, and, because of failure to isolate most such infected patients, the infecting organisms are probably disseminated in enormous numbers They may be transferred directly from patient to patient or from patients to personnel on contaminated (though grossly clean) hospital blankets (which are often not laundered for six months or more) serving many patients during this period[11] Even when laundered, blankets may remain contaminated[12] Hospital mattresses may be another important reservoir of antibiotic-resistant bacteria[9] Thus, numerous opportunities for cross-infection of micrococcic infections exist in hospitals and provide an adequate explanation for the prompt appearance of infections resistant to multiple antibiotics The very fact that most hospital-acquired antibiotic-resistant infections are probably the result of cross-infection, however, implies that such infections are largely or entirely preventable

Over half of the infections reported in this series appeared in hospitalized patients and thus may have been preventable These were the more serious infections and caused most deaths related to infection Also possibly avoidable were the 32 infections appearing within 60 days of hospital discharge Most of the organisms isolated from this group (91%) showed patterns of antibiotic resistance unusual for organisms causing infections acquired before hospital admission and resembling the antibiotic-resistant patterns of organisms isolated in infections appearing in hospitalized patients The interval of less than 60 days from hospitalization to infection is within what may be termed the latent period of micrococcic infection Investigations of neonatal micrococcic infections in Seattle and elsewhere, utilizing bacteriophage typing, have produced evidence that micrococcic infections acquired in hospitals may remain latent for several months before producing clinical disease[13] It is probable that most of the 32 infections appearing within 60 days of hospital discharge were acquired as a consequence of hospital admission

Comment

The results of this study appear to indicate that, at the present time, micrococcic infections acquired outside the hospital do not merit great concern An average of 16 such infections, proved by culture, appeared per month, with one death every two months In contrast, if we include infections appearing within 60 days of discharge, infections evidently resulting from hospitalization in this 350-bed hospital averaged 38 cases per month (4% of the monthly average of 994 hospital admissions and births), with 6 deaths each month related to such infections If this rate were maintained for a year, there would be a total of 450 cases and 76 deaths This is nearly equal to the annual incidence of poliomyelitis in the entire state of Washington in the years prior to 1956 (with deaths from poliomyelitis much fewer) Presuming that micrococcic infections are acquired in other hospitals in the state also, it is clear that these infections may be the most serious communicable disease problem in this state—and probably in other states as well

The tabulation of infections in this study presumably underestimates the actual incidence of micrococcic disease in this hospital However, since this is a county hospital caring chiefly for indigent patients, it is probable that a far higher proportion of patients are elderly and debilitated than in most private hospitals Also, crowding of patients tends to be greater in public than in private hospitals Debilitation and crowding predispose to micrococcic infections Thus it would be anticipated that the incidence of micrococcic infection in most private hospitals would not be comparable to the incidence encountered during this investigation

A cause of concern nearly equal to the total incidence of hospital-acquired infections has been the apparently increasing resistance of such infections to antibiotic therapy and the problems of clinical management which have ensued Until the latter part of 1955, infections caused by organisms sensitive only to bacitracin were virtually unknown in this hospital Yet in our series of patients whose infections appeared within the hospital or after discharge, over 20% of the organisms cultured were resistant to all of the currently used antibiotics except bacitracin In this group of 28 patients, 12 deaths occurred, all related to infection (table 2)

In addition to complicating the task of treating micrococcic infection, the appearance of highly resistant organisms decreases the possible value of prophylactic chemotherapy in the postoperative management of surgical patients Not only is such chemotherapy likely to selectively permit growth of the more resistant bacteria, but there would currently seem to be less chance for prophylactic therapy to succeed if penicillin, streptomycin, or a tetracycline is used Reemphasis on strict aseptic technique, including preoperative and postoperative patient care, appears indicated

This study permits certain generalizations concerning the types of patients most vulnerable to micrococcic infection and thus points out areas in which greatest care is needed Clearly, any break in the skin, surgical or traumatic, including that made by intravenous catheters, appears to open the way for micrococcic invasion Debilitated patients, especially those in coma, are evidently unusually susceptible to pneumonia and skin infection Newborn infants appear to have very little resistance to micrococcic infection, and invasion may take place through normal, intact skin These considerations should not suggest more prophylactic therapy for susceptible persons but rather greater attention in preventing cross-infection by keeping the patient's environment as free as possible from pathogenic organisms and by careful observation for signs of clinical infection

This general approach to preventing micrococcic infections may be elaborated in terms of certain specific measures Micrococcic infections are probably contagious, and consequently patients with such infections should be isolated whenever possible for the protection of both patients and personnel [14] Contaminated bedding, from which large numbers of micrococci may be disseminated into the air, could serve as an important cause of nasal carriers among personnel,[1a] of micrococcic pneumonia, of skin infections, and of infections of poorly healing wounds Thus, it would appear that mattresses should be effectively covered and the covers cleaned between change of patients and that blankets should be laundered frequently and preferably sterilized with each laundering These and other preventive measures have recently been reviewed in greater detail by Starkey [15] and Howe [3a]

Such measures to control infections have a sound basis in our current knowledge of micrococcic epidemiology Their application should be encouraged by the realization that hospital-acquired infections seem largely preventable This realization should also provide stimulus to further investigation of the complex epidemiology of such infections and thus to more effective control

Summary

The cases of 189 patients with micrococcic (staphylococcic) infections, occurring during a period of three and one-half months, were investigated In 100 cases the infections appeared during hospitalization, and in 32 they appeared within 60 days of discharge from the hospital The remainder were acquired before hospital admission The infections investigated included 37 infections of surgical wounds and 14 of micrococcic pneumonias Twelve of the patients had micrococcic bacteremia, six of them died

In the entire group of 189 patients, 24 deaths occurred, with micrococcic infections a contributing factor in each case Twenty-one of the deaths were in the group of patients whose infections appeared during hospitalization In 28 of the 132 infections (21%) which were probably acquired as a result of hospitalization, the causative organisms were sensitive only to bacitracin Studies with bacteriophage typing indicated that a variety of strains of micrococci were isolated from infections except in puerperal and neonatal infections, in which a single bacteriophage type, 52/42B/44A, appeared to be responsible for most infections

Most of the micrococcic infections which appeared during hospitalization or shortly after discharge were the result of cross-infection within the hospital Such infections are theoretically preventable, and the following of preventive measures is urged

ISONIAZID AS A CAUSE OF OPTIC NEURITIS AND ATROPHY

Irving Kass, M D, William Mandel, M D, Henry Cohen, M D
and
Sidney H Dressler, M D, Denver

• The most frequent toxic symptoms and signs following isoniazid therapy are secondary to involvement of the nervous system In addition to these usual toxic manifestations, two cases of bilateral optic atrophy occurred after the use of isoniazid In one of these cases discontinuance of use of the drug brought reversal of the process Two other similar cases have been reported Isoniazid optic neuritis and/or atrophy does not seem an example of drug idiosyncrasy, but rather part of the commonly found toxic neuritis associated with use of this drug All patients receiving isoniazid should be given pyridoxine An ophthalmological examination should be conducted whenever visual complaints are voiced

The incidence and types of toxic effects following isoniazid therapy have been difficult to define accurately because of the nature of the complaints as well as the varied approaches by different observers The most frequent toxic symptoms and signs are secondary to involvement of the nervous system These include dryness of the mouth, transient diplopia, heartburn, flatulence, delayed micturition, vertigo, dizziness, paresthesias, numbness, muscle twitching, hyperreflexia, headaches, burning feet, and mood disturbances[1] It appears that malnourished individuals, chronic alcoholics, and persons with preexisting cerebral damage (as in epilepsy), are particularly prone to the neurotoxic effects of isoniazid[2]

Optic disturbances secondary to isoniazid therapy have not been frequently recorded Janssen and Boke[3] observed an increase in optic lesions in patients with tuberculous meningitis who were treated by the intrathecal administration of isoniazid with streptomycin as compared with those treated by the intrathecal administration of streptomycin alone Sutton and Beattie,[4] in 1955, reported one case of bilateral optic atrophy following the use of isoniazid, and, later that year, Keeping and Searle[5] reported an instance of bilateral optic neuritis following the use of isoniazid We have observed two cases of bilateral optic atrophy, in one, discontinuation of isoniazid therapy brought reversal of the process Since it is not generally known that such lesions result from use of isoniazid, it is felt that presentation of these cases, along with a review of some aspects of isoniazid toxicity, is warranted

Report of Cases

CASE 1 —A 50-year-old woman was admitted to the hospital in March, 1955, for further treatment of pulmonary tuberculosis Her illness dated to 1935, when she first became ill with tuberculosis involving the left lung At that time crushing of the left phrenic nerve was done, and after two years of bed rest the patient was discharged The tuberculosis reactivated in 1948, and the patient was treated with streptomycin for two months and with therapeutic pneumothorax of the right lung for four years In September, 1952, she received 300 mg or 5 mg per kilogram of body weight, of isoniazid daily for one month In July, 1953, isoniazid therapy was restarted, using the same dosage, and was continued until the patient was admitted to this hospital The patient had a strong family history of tuberculosis She did not drink alcoholic beverages and had smoked 10 to 15 cigarettes daily for many years

Physical examination revealed a well-developed woman who appeared chronically ill The blood pressure was 96/60 mm Hg, pulse 82 per minute, and temperature 99 F (37 2 C) The right hemithorax was smaller than the left There were diminished breath sounds over the right side of the chest, and coarse rales were heard over the apex of the right lung The heart, though shifted to the right, was normal There was slight tenderness of the left calf muscle The remainder of the physical examination was normal The hemoglobin level, hematocrit reading, leukocyte and differential counts, urinalysis, and blood serology were normal or negative The sedimentation rate was 22 mm per hour A chest roentgenogram showed a small vertical heart displaced to the right There was marked pleural thickening in the right hemithorax and moderate fibrous calcification of the apex of the left lung Emphysematous changes were present throughout both lung fields

When the patient was admitted to the National Jewish Hospital at Denver, in March, 1955, the isoniazid dosage was increased to 900 mg, or 16 mg per kilogram, daily, and she also received 100 mg of pyridoxine and 100 mg of thiamine daily Six weeks later, she complained of dizziness as well as numbness and tingling in her lower extremities The isoniazid dosage was reduced to 450 mg, or 8 mg per kilogram, daily One week later, the patient experienced tingling and numbness in her hands and complained of diminution of vision Isoniazid therapy was discontinued at this time

Examination by an ophthalmologist revealed a visual acuity of 14/200 in both eyes The ocular tension was 16 9 mm Hg in both eyes The right optic disk was redder than normal on the nasal side and showed some pallor on the temporal side There was a circular ring of pigment about the disk The remainder of the fundus appeared normal The left disk was similar, though the changes were not as marked, and the zone of pigmentation was not observed There was a normal response with the 3-mm white target A concentric constriction of the visual fields more marked on the right, was present with the 1 mm white target The findings were consistent with the diagnosis of optic neuritis associated with early atrophy Three weeks later, there was an increase in the concentric constriction of both visual fields, again more marked on the right No special treatment was given There was a steady and gradual improvement in vision as well as lessening of the paresthesias On reexamination of the patient six months later, the ophthalmological findings were completely normal

This 50-year-old woman developed bilateral optic neuritis and early optic atrophy associated with peripheral neuritis within two months after her daily dosage of isoniazid was increased from 5 to 16 mg per kilogram After discontinuation of isoniazid therapy, her symptoms improved gradually, and within six months she had recovered fully A microbiological assay for serum isoniazid, performed six hours after a test dose of 4 mg of isoniazid per kilogram

---

From the National Jewish Hospital at Denver (Drs Kass, Mandel, Cohen, and Dressler) and the University of Colorado School of Medicine (Drs Kass, Mandel, and Dressler) Dr Mandel is now in San Francisco and Dr Cohen at the Davidson County Hospital, Nashville, Tenn

showed 1 6 mcg per cubic centimeter This is considered to be a high level of biologically active isoniazid,[6] indicating that the patient did not inactivate this drug rapidly

Case 2—A 64-year old man was admitted to the Veterans Administration Center Wadsworth, Kans, on Oct 18, 1954 He had a history of generalized weakness and weight loss of 30 lb (14 kg), extending over several months He was disoriented, and an accurate history could not be obtained, though it was known that he was a chronic alcoholic His previous illnesses had included bronchitis, meningitis, smallpox, pertussis and influenza Physical examination revealed a malnourished, chronically and acutely ill patient The complete physical examination revealed no other significant abnormalities except loss of vibratory sensation in the lower extremities The initial chest roentgenogram revealed a cavity with surrounding infiltration in the upper part of the left lung The leukocyte count was 13 800 per cubic millimeter with a differential count of 86% neutrophils 13% lymphocytes, and 1% monocytes The sedimentation rate was 26 mm per hour The hemoglobin level, hematocrit reading blood glucose level, carbon-dioxide content and nonprotein nitrogen serum potassium and calcium levels were normal a serologic test for syphilis was negative The serum sodium level was 130, and the serum chloride level was 92 mEq per liter The serum inorganic phosphorus level was 1 8 mg the total serum protein level 4 9 Gm, and the serum albumin level 3 1 Gm per 100 cc The total serum cholesterol level was 90 mg with cholesterol esters 33 mg per 100 cc The spinal fluid pressure and dynamics were normal The cell count and glucose chloride and protein content of the spinal fluid were normal The colloidal gold reaction and serology were negative A skin test with intermediate-strength purified protein derivative was positive, skin tests for histoplasmosis, coccidioidomycosis, and blastomycosis were negative Repeated examinations of the sputum were negative for acid fast bacilli

A tentative diagnosis of tuberculosis was made, and treatment with isoniazid in a daily dosage of 400 mg or 9 mg per kilogram was started Thirty days after the start of isoniazid therapy the patient complained of severe retro orbital pain on the left On the following day, he was aware of visual loss in the left eye that progressed rapidly to complete blindness Within four days, similar involvement of the right eye occurred The use of isoniazid was discontinued and the patient was treated with vasodilators His condition deteriorated rapidly, two months after admission to the hospital he developed bronchopneumonia and he died on Dec 17, 1954

Examination by an ophthalmologist, after the onset of visual difficulties had revealed complete loss of vision as well as an absence of direct and consensual light reflex in the left eye There was diffuse retinal blurring, but no hemorrhages or exudate were present One day later, a 1-to 2-D papilledema was observed in the left eye There were no extraocular muscle disturbances Four days after onset of visual difficulties, the right pupil became fixed and the borders of the disk were poorly defined The diagnosis of an acute fulminating optic neuritis was made Skull roentgenograms, bilateral carotid arteriograms and a pneumoencephalogram were normal An electroencephalogram showed definite abnormalities which were not characteristic of any specific lesion but which were consistent with generalized organic disturbance Prior to the patient s death, ophthalmological changes consistent with a bilateral optic atrophy were observed

Postmortem Examination—At autopsy it was found that the apex of the left lung was firmly bound to the chest wall and the right pleural cavity was obliterated by fibrous adhesions The apex of the left lung contained a single thin-walled cyst measuring 9 5 cm in its greatest diameter The brain weighed 1,725 Gm The convolutions and sulci were not flattened The cerebral hemispheres were symmetrical The brain was firm in consistency, and coronal sections failed to demonstrate any dilatation of the ventricular systems The lining of the anterior horn of the left ventricle was somewhat flattened, and numerous petechial hemorrhages were observed Sections of the cerebral hemispheres showed prominent vascular markings The brain stem was not remarkable

Microscopic examination of sections from the cavity in the upper lobe of the left lung showed that it was lined, in part by respiratory epithelium In other zones, the lining was ragged and neutrophils and fibrin were present The wall of the cavity consisted of cellular fibrous tissue moderately infiltrated by lymphocytes and plasma cells A few multinucleated giant cells were found Sections of the anterior horn of the left lateral ventricle of the brain showed that it was lined by an ependyma containing granulations The ependymal lining was interrupted and had an irregular surface that showed numerous petechial hemorrhages The adjacent parenchyma showed increased vacuolation Sections through the optic nerve were not remarkable There was some piling of the arachnoid cells and a moderate focal fibrous thickening of the meninges was present The anterior lobe of the pituitary gland was not remarkable but sections of the posterior lobe were pigmented

The final diagnoses were blindness toxic in origin broncho pneumonia and cyst of the left lung congenital in origin

This 65-year old male chronic alcoholic was admitted to the hospital in a state of advanced malnutrition Because of the possibility of tuberculosis, he was treated with isoniazid After 30 days of therapy, he developed optic neuritis in the left eye and then in the right eye This progressed rapidly to optic atrophy and complete blindness The patient s condition deteriorated rapidly, and he died within two months after hospitalization Although the etiology of the optic changes was not specifically known, it was felt that the disturbances were precipitated by the isoniazid therapy

Comment

Sutton and Beattie,[4] in 1955, were the first to report the occurrence of optic atrophy after the administration of isoniazid Their patient complained of loss of vision 10 days after receiving 200 mg of isoniazid and 15 Gm of aminosalicylic acid daily Little attention was paid to these symptoms because visual disturbances resulting from isoniazid therapy had not been reported previously, and the medication was continued for six weeks The visual difficulties persisted and progressed to bilateral optic atrophy The authors speculated that the optic atrophy was related to a drug idiosyncrasy secondary to isoniazid Aminosalicylic acid was not implicated because the patient had received this drug previously without ill-effects Keeping and Searle,[5] in the same year, reported the onset of optic neuritis, secondary to isoniazid Their patient complained of visual loss 25 days after first receiving 1 Gm of streptomycin and 200 mg of isoniazid daily Six weeks later, a diagnosis of bilateral optic neuritis was made and the medication was discontinued After this, there was a rapid return of the patient s vision to normal These authors again stressed the rarity of an optic neuritis following isoniazid therapy and suggested that a drug idiosyncrasy was the precipitating cause

Our report of two cases of optic disturbance during the administration of isoniazid brings the total of such cases to four The onset of visual difficulties occurred within one month after initiating therapy in three cases, and within two months after a marked increase in the dosage in the fourth case There were no other known causes for the optic involvement in three of the four patients In one of our cases, the patient was a markedly malnourished alcoholic, and it may be fair to question the role of isoniazid in his optic changes

With so few cases reported, it is possible that the visual lesions occurred by chance in these patients receiving isoniazid This seems unlikely when one considers not only the known neurotoxicity of isoniazid but the fact that the patient of Keeping and Searle, as well as one of ours, improved remarkably after isoniazid therapy was discontinued In addition, and of importance, there was the association of peripheral neuritis and optic neuritis in one of our patients These lesions occurred at the same time, and both gradually improved when isoniazid therapy was stopped

Mechanism of Neurotoxicity—It is our impression that isoniazid optic neuritis and/or atrophy due to isoniazid is not an example of drug idiosyncrasy, as suggested by others, but that it is part of the toxic neuritis commonly found with use of this drug The reason for the rarity of this condition when compared to the incidence of peripheral neuritis in patients receiving isoniazid is unexplained Since studies have been conducted on the causes and prevention of peripheral neuropathy following isoniazid therapy, a discussion of these findings may be useful in defining the relationship between isoniazid therapy and optic disturbances Because similar symptoms occur with states of nicotinic acid deficiency as with isoniazid intoxication, it was suspected that the peripheral neuritis related to isoniazid therapy resulted from a competitive inhibition of nicotinic acid Vilter and co-workers[7] felt that this was unlikely, since they found normal urinary values for nicotinic acid and its derivatives in patients showing severe toxic effects from isoniazid Biehl and Vilter[8] found that isoniazid therapy caused a marked urinary loss of pyridoxine, which reverted to normal when isoniazid therapy was stopped Pyridoxine-deficiency states in man, produced by pyridoxine-deficient diets or by use of metabolic antagonists, may produce peripheral neuritis[9] Symptoms of these types of induced pyridoxine deficiency include glossitis and dermatitis which are not unlike those conditions produced by isoniazid in some patients Degenerative changes of the peripheral nerves, thoracic root ganglion cells, and posterior columns of the spinal cord have been described in pigs deficient in pyridoxine[10]

Biehl and Nimitz[11] reported that pyridoxine, in dosages of 50 to 450 mg daily, prevented the appearance of peripheral neuritis secondary to high dosages of isoniazid Carlson and co-workers[12] reported that the administration of pyridoxine with isoniazid decreased the incidence of peripheral neuritis and permitted the administration of high dosages of isoniazid for longer periods of time The experimental and clinical evidence suggests that isoniazid alters the metabolism of pyridoxine and thus could produce both the peripheral and optic changes

The degree to which isoniazid is altered by metabolic processes may have some relationship to the neurotoxicity of the drug That portion of the drug which escapes inactivation, the biologically active moiety, appears to be responsible for the toxic effects of isoniazid Our experience in other studies[13] suggests that the severe toxic reactions have occurred in those patients who, as a result of the retarded isoniazid inactivation, maintain a higher serum level of the biologically active moiety Although the amount of biologically active isoniazid present on the same drug dosage varies markedly from person to person, it remains relatively constant for a given individual[14] We have observed that the level of biologically active isoniazid is increased in most patients by the simultaneous administration of aminosalicylic acid, which probably acts by competing with isoniazid for acetylation[15] The amount of biologically active isoniazid present is also increased by increasing the dosage of isoniazid Biehl and Nimitz[11] observed that 44% of the patients who received 16 to 24 mg of isoniazid daily per kilogram developed peripheral neuritis This occurred in 20% of the patients receiving 11 to 15 mg per kilogram daily and in only 8% of those receiving 6 to 10 mg per kilogram daily

As indicated by the above, the patients who are most likely to develop neurotoxic effects from isoniazid are those who (1) inactivate isoniazid slowly or receive high dosages, (2) receive both aminosalicylic acid and isoniazid, and (3) have not been given pyridoxine

Two of the four patients who developed optic neuritis or atrophy were receiving high dosages of isoniazid, and one of them was known to inactivate isoniazid slowly A third patient was receiving aminosalicylic acid in addition to isoniazid Only one of the four received pyridoxine

Since serious visual disturbances may follow the use of isoniazid, it is imperative that ophthalmological examinations be conducted whenever visual complaints are voiced This is important in view of the fact that the optic lesions are likely to be reversible if isoniazid therapy is discontinued promptly All patients receiving isoniazid should be given pyridoxine in a dosage of 25 to 100 mg daily to reduce the incidence of neurotoxic effects from isoniazid

Summary

In two cases, optic neuritis and, eventually, atrophy occurred after the use of isoniazid Serious optic disturbances attributable to isoniazid have been reported in a total of four cases, including these two It is assumed that the optic lesions are part of the neurotoxic effects of isoniazid and, though rare, do not represent an unusual form of drug idiosyncrasy The cause and treatment of peripheral neuritis due to isoniazid have a bearing on the problem of optic neuritis due to isoniazid The physician should be aware that serious visual lesions may follow the use of isoniazid If all patients receiving isoniazid are given pyridoxine daily, the incidence of neurotoxic effects will be reduced

PERFORMANCE OF CESAREAN SECTION WITH AID OF GENERAL ANESTHESIA

ANALYSIS OF ONE THOUSAND ELEVEN OPERATIONS SINCE 1948

Herman L Allen, M D, Augustine S Weekley, M D
and
DeForest W Metcalf, M D, Youngstown, Ohio

• *Experience with the cyclopropane curare type of general anesthesia in 1,011 cesarean sections has been analyzed and compared with published reports on the use of other types of anesthesia for this operation All patients in this series received scopolamine with or without additional premedication, and after the induction of anesthesia with cyclopropane an injection of 6 to 12 mg of tubocurarine chloride was given intravenously The one maternal death in this series occurred two weeks after the operation and was not related to the anesthesia The associated gross infant mortality rate was 5 4%, of which 2 9% were stillbirths and 2 5% were neonatal deaths, but when this figure was corrected for prematurity, congenital anomalies, and other factors clearly unrelated to the anesthesia, the net rate was 4 7%, with 2 4% for stillbirths and 2 3% for neonatal deaths These findings conflict with claims that have been made for the superiority of other methods of anesthesia The good results here reported are ascribed in part to the care and observation given to the individual patient before the operation as well as to the attention given in the recovery room It is therefore recommended that trained anesthesiologists be kept available for obstetric patients throughout the 24 hour day*

There is no one method of anesthesia for cesarean section that is superior to all other methods Recent literature[1] has indicated that better results are to be obtained with regional anesthesia than with general anesthesia in cesarean sections In order to evaluate the validity of such statements, it was decided to review the cesarean sections done by us since 1948, 99% of which were performed with the patient under general anesthesia with cyclopropane and curare

This study is a report of 1,011 cases of cesarean section performed with the patient under general anesthesia The period covered is from Jan 1, 1948, through April 30, 1956, and includes a large number of sections performed within the modern era of surgery and anesthesia

The cesarean sections in this study were performed within the North Side Unit of the Youngstown Hospital, Youngstown, Ohio, which comprises one of the two maternity services located in the city The hospital is essentially a private hospital, with service cases representing less than 5% of the total number of deliveries Delivery privileges are extended to general practitioners, who conduct approximately half of the annual deliveries However, the cesarean sections are performed exclusively by physicians who are diplomates of the American Board of Obstetrics and Gynecology or who are qualified for certification by that board

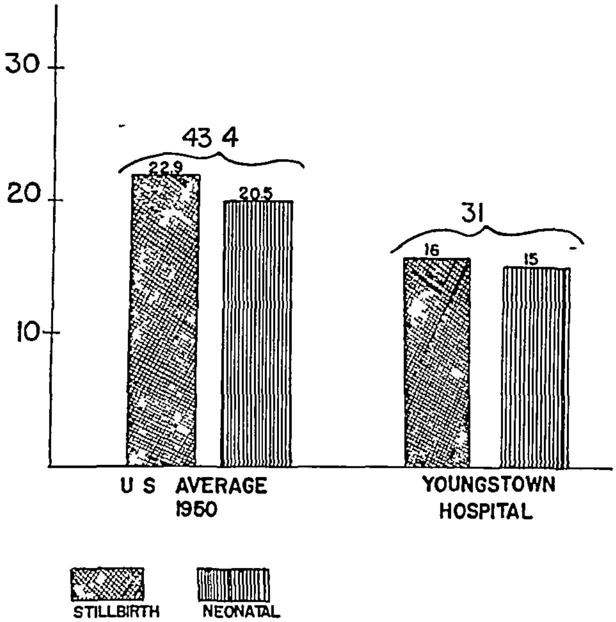
Anesthesia for all cesarean sections is conducted by or under the direct supervision of a physician who has had full residency training in anesthesiology and is a member of or in the process of fulfilling requirements for certification by the American Board of Anesthesiologists

Method

The anesthetic technique used is the cyclopropane-curare method introduced for cesarean sections in 1947 by Whitacre and Fisher[2] All patients are seen

---

From the Department of Anesthesia, Youngstown Hospital Association preoperatively by an anesthesiologist for a general preoperative evaluation and also for indoctrination of the patient as to the method used The sequence of events to be followed in the operating room is outlined to the patient, since, with the technique used, anesthesia is not induced until immediately before the incision is to be made At this time orders are written for the typing and cross-matching of blood for the patient All patients have blood ready for them preoperatively Blood is administered preoperatively as indicated Food and orally given fluids are withheld before elective section, as with any major surgery, and also at the onset of labor in all obstetric patients



Graph showing perinatal mortality per 1 000 live births in Youngstown Hospital as compared with average in United States in 1950 Data on United States average from Potter[3]

Preoperative Medication—From 1948 to 1954 the patients received only a belladonna derivative for preoperative medication Since 1954 we have been giving our patients two hours preoperatively a barbiturate (100 mg), levorphanol (Levo-Dromoran) tartrate (1 mg), and scopolamine (0 4 mg)

Anesthesia in the Operating Room—After the patient is draped and the surgical staff is completely gowned, anesthesia is induced with cyclopropane After induction is complete, 6-12 mg of tubocurarine chloride is administered intravenously The incision is made approximately one minute after the curare compound is administered There is frequently a minimal flexor response in the patient as the incision is made, but we have not had any patients recall a painful experience postoperatively The flexor response is desirable and indicates a proper level of anesthesia Respirations are assisted as indicated After the delivery of the baby, which is usually six to nine minutes after the onset of anesthesia, the level of anesthesia is deepened and maintained, as for any other surgical procedure

Postoperative Care—All infants receive nasal and pharyngeal suctioning with a soft rubber catheter immediately after delivery Infants with any degree of respiratory embarrassment are immediately seen and treated by an anesthesiologist All patients are taken to the recovery room postoperatively and are observed there until their conditions are completely stabilized and they are awake

Results

During the period covered in this study, there were 32,238 deliveries, of which 1,011 were cesarean sections conducted with the patient under cyclopropane curare anesthesia

The figure presents data on the over-all fetal mortality on our obstetric service as compared with reports in the recent literature[3] There were 507 stillbirths and 462 neonatal deaths in this series, giving a gross, uncorrected fetal loss of 3% For this period, there were 16 stillbirths and 15 neonatal deaths per 1,000 live births

There were 10 maternal deaths on our obstetric service during this period, giving a maternal mortality rate of 1 per 3,100 live births In 1950 in the United States the average maternal mortality rate was 1 5 per 1,000 live births Thus, the maternal mortality rates per 10,000 live births in all of the United States and on our obstetric service were 15 and 3 3 respectively In the series of cesarean sections, there were no maternal deaths associated with anesthesia There was one maternal death in this series, which occurred two weeks after cesarean section and was secondary to intestinal perforation and peritonitis

Associated with cesarean section, there was a gross infant mortality rate of 5 4%, of which 2 9% were stillbirths and 2 5% were neonatal deaths The criteria for correction for fetal and neonatal mortality are (1) congenital anomalies judged to be incompatible with survival, (2) fetus of less than 1,000 Gm (2 2 lb), (3) estimated gestation of less than 28 weeks, (4) evidence suggestive of intrauterine death before section, and (5) evidence at section of intrauterine death before section, such as macerated fetus If these criteria are used rigidly, the corrected infant mortality rate is 4 7%, of which 2 4% were stillbirths and 2 3% were neonatal deaths

Indications for Cesarean Section and Total Associated Perinatal Deaths, with Percentages of Stillbirths Versus Neonatal Deaths

	No of Cases	Stillbirths %	Neonatal Deaths %
Abruptio placentae	15	87	13
Placenta praevia	11	28	72
Previous section	6	50	50
Cephalopelvic disproportion	3		100
Toxemia	5	20	80
Miscellaneous maternal distress	5	60	40
Miscellaneous fetal distress	1	100	
Erythroblastosis fetalis	1		100
Uterine inertia and dystocia	4	75	25
Prolonged labor	1		100
Abnormal presentation	1	100	
Prolapsed cord	2	100	

The table lists the perinatal deaths associated with various indications for cesarean section and compares the incidence of stillbirth versus neonatal death, in order to determine the relationship of indication for cesarean section with the chance of a stillbirth or neonatal death It can be noted quite readily that abruptio placentae, as expected, is associated with a markedly high incidence of stillbirths

Comment

A review of the literature will demonstrate that various methods of anesthesia have been used in cesarean sections, such as regional,[4] general,[5] and intravenous[6] The results obtained by the different methods are quite variable, but it can be noted that good results are possible by the use of all methods by trained anesthesiologists This study was undertaken to review the results of a large series of cesarean sections done by one method of anesthesia (cyclopropane and curare)

As indicated by the results noted above, the use of cyclopropane and curare has been a highly successful method of anesthesia for cesarean section in our hands There were no maternal deaths attributed to anesthesia in this large series, and, from all causes, there was only one maternal death, giving results comparable to those reported by Lull and Ullery,[4d] who used spinal anesthesia The claim by the proponents of conduction anesthesia that general anesthesia will produce an increase of perinatal and maternal mortality is not borne out by this study The maternal mortality rates for cesarean section in the recent literature range from 0 08% to 5 82%[7] The perinatal mortality rates associated with this operation range from 2 96% to 22%[8]

The problem of aspiration of vomitus is an ever-present one for the anesthesiologist regardless of the method of anesthesia We feel it is not a problem to be feared but one to be respected Aspiration of vomitus has not been a problem in our series The light level of anesthesia, close observation of the patient, and prompt and adequate therapy, we feel, have prevented the occasional patient who vomits from getting aspiration pneumonia

It is well to note that the ultimate statistics that are derived in the study of any anesthetic method are markedly affected by the type of patient that is presented to the anesthesiologist for anesthesia Close observation, good therapy, and adequate consultation service on the part of the obstetric department present more patients in optimal condition for anesthesia and, thereby, produce much better results If there is a weak link in the obstetric care of the patient, then the condition of the candidate for anesthesia will be much worse and the results will be poor even though the anesthesia be of equal quality

A word about the literature on cesarean section studies is warranted because of the abundance of small series with large conclusions in the literature The practice of deriving results from a small series is dangerous, as the standards of comparison are in the realms of a few per cent to fractions of a per cent It is obvious that one or two bad results can change the statistics discussed markedly, and, in order to arrive at valid conclusions, a large series of cases treated by a single method must be reported There is no doubt that, in order to obtain good results by any method of anesthesia, 24-hour hospital coverage by trained anesthesiologists is required The practice of inducing good anesthesia in the patient who is undergoing cesarean section between 8 a m and 5 p m and then allowing the emergency patient to be handled by emergency personnel can only tend to produce poor results Regardless of the method of anesthesia used, there must be close liaison between the obstetrician and the anesthesiologist Since anesthesia for cesarean section is concerned with two lives, there are times when the operator must change his technique to fit the anesthetic method of choice or the anesthesiologist must change his method to fit the operative technique of choice Any one method cannot fit all cases or operations, but by mutual consultation and education between the obstetrician and anesthesiologist a combination can be obtained that is best for the individual patient

Summary

A review of anesthesia with cyclopropane and curare, administered by or under the direct supervision of trained anesthesiologists, in 1,011 cesarean sections performed in the Youngstown Hospital since 1948 indicates that in trained hands one method of anesthesia is not superior to all other methods of anesthesia No maternal mortality associated with anesthesia occurred in this series There was one maternal death secondary to intestinal perforation and peritonitis The corrected perinatal mortality rate was 4 7% Abruptio placentae is associated with the greatest incidence of stillbirths

Good results for anesthesia are directly proportional to the care and observation the patient receives prior to the operation, and significant reduction in mortality and morbidity demands precise attention during operation and a well-run recovery room

Twenty-four-hour coverage by trained anesthesiologists is mandatory for good results

INTRAMEDULLARY FIXATION OF METACARPAL FRACTURES

Richard E Lord, M D, St Louis

• *The treatment of fractures by inserting longitudinal intramedullary wires for fixation has been applied in 30 patients with metacarpal fractures Local anesthesia was obtained for fractures of the fifth metacarpal (80% of this series) by blocking the ulnar nerve, which is easily accessible at the elbow Reduction is accomplished with direct pressure over the fracture toward the palm of the hand and counter pressure dorsally on the flexed proximal phalynx The wire or pin is gently drilled longitudinally through the soft surface of the head and should run the full length of the bone so as to engage the proximal end and produce adequate fixation In most cases bony union has been solid enough in three weeks to remove the wire The patients have been able to return to work at once, and no infections or refractures have occurred*

In the ever-advancing field of orthopedic surgery, intramedullary fixation is gaining in popularity This principle has been used in almost every part of the body to maintain fracture fixation and yet allow a more normal physiology of the part to exist The freeing of joints from plaster fixation and the reduction of economic loss to the patient have been most appealing These same advantages may also be applied to fractures of the metacarpals in a simple but effective manner

Metacarpal fractures rank second among the most common fractures of the hand and fingers In a large military installation, such as the Keesler Air Force Base, Mississippi, from whence most of this series was compiled, metacarpal fractures resulting from fisticuffs and from direct trauma to the hand are frequently encountered

Locations of Metacarpal Fractures

Location	No	Percentage
Fifth metacarpal		
Neck	19	63 } 80
Shaft	5	17 } 80
Fourth metacarpal		
Shaft	3	10
Second metacarpal		
Shaft	3	10

It has been shown by Sutro,[1] Norman,[2] and Berkman[3] that the above advantages of intramedullary nailing apply to the metacarpals They advocate transverse metacarpal wiring to fix the fragments Aside from the technical difficulty of transverse wiring, this method has been found to affect the efficiency of the intrinsic muscle mechanism

Closed reduction and plaster fixation has been recommended by Bunnell[4] This procedure, except in the most skilled of hands, frequently results in finger-and-hand stiffness, malunion, necrotic skin areas, and great economic loss

A more physiological method, that is, longitudinal intramedullary wire fixation, seems to serve this purpose best It offers good stability, simplicity of insertion and removal of pins, and no physiological impairment of muscle mechanism of the hand The series treated was composed of 30 patients with fractures of the metacarpals, 80% being of the fifth metacarpal, 10% of the second metacarpal, and 10% of the fourth metacarpal

Anesthetization

Ulnar nerve block at the elbow was used on 24 fractures of the fifth metacarpal This has proved to be a valuable adjunct to the success of this simple procedure It facilitates success for several reasons

1 There is no need for the administration of a local anesthetic at the fracture site, which, if used, would obliterate the bony landmarks necessary for pin insertion

2 This method of blocking allows the procedure to be done anywhere that sterile conditions can be obtained

3 It is easy to find the ulnar nerve for nerve block, since it lies subcutaneously between two bony landmarks In most instances the nerve can be palpated with the index finger (fig 1)

When 10 cc of a 1% solution of lidocaine (Xylocaine) hydrochloride is used, a definite numbness can be obtained This will allow ample time for pin insertion and for the taking of x-rays if they are needed It is important that approximately 20 to 30 minutes elapse between the injection of lidocaine and the reduction of the fracture of the fifth metacarpal This time may be spent in preparing the hand for surgery

The median and radial nerves may be blocked just above the wrist in the case of fractures involving the other four metacarpals

Pin Insertion

After successful anesthetization, the fracture is reduced, with the metacarpophalangeal joint flexed to 90 degrees and pressure applied in a dorsal direction upon the flexed finger Counterpressure is applied on the dorsum of the hand, the fracture site being pushed toward the palm These forces reduce the fracture (fig 2)

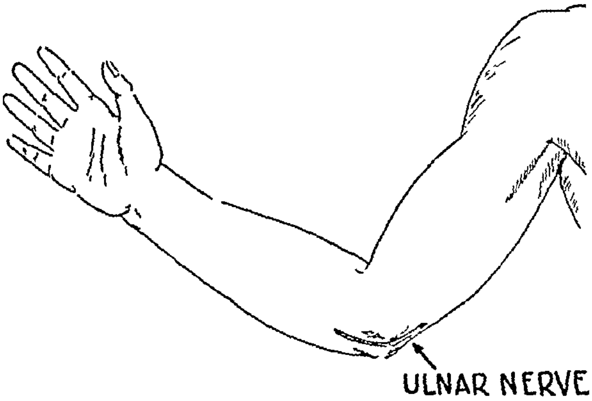

Fig 1—Ulnar nerve at elbow lies in a bony groove and is easily found for nerve block

The fracture is held in this position by an assistant A 0 062-gauge plain Kirschner wire is used The wire is introduced through the skin where it meets the distal articular surface of the head of the metacarpal (fig 3) The extensor tendon slides toward the radial side of the metacarpal head, when the metacarpophalangeal joint is flexed to 90 degrees, and so stays out of the way of the pin during this procedure The pin is gently drilled through the soft cartilaginous-bony surface of the head (fig 4) It should run the full length of the metacarpal and engage its base to produce adequate fixation Entry into the carpometacarpal joint seems to cause no ill effects

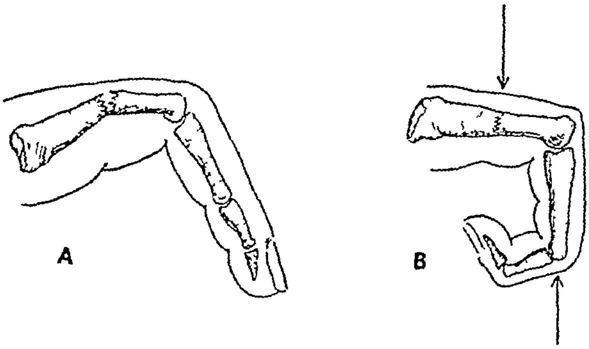

Fig 2—A, fracture of shaft of the metacarpal presents dorsal angulation of bone at fracture site, 'knuckle' is accordingly depressed B, two simple forces are needed to reduce fractures of either neck or shaft of the metacarpal They are (1) pressure toward palm over fracture site and (2) counterpressure in dorsal direction on flexed proximal interphalangeal joint

X-rays are then taken In the case of a neck fracture of the fifth metacarpal, there is so little danger of the pin leaving the intramedullary canal that it is not necessary to take x-rays in the operating room Shaft fractures are more difficult, and x-rays on the operating table should be made

After satisfactory insertion, the pin is cut at a level just beneath the skin This usually leaves about ¼ in of pin extending subcutaneously from the articular surface, which insures easy removal No plaster is needed, and the patient is allowed to return to duty immediately (figs 5 and 6)

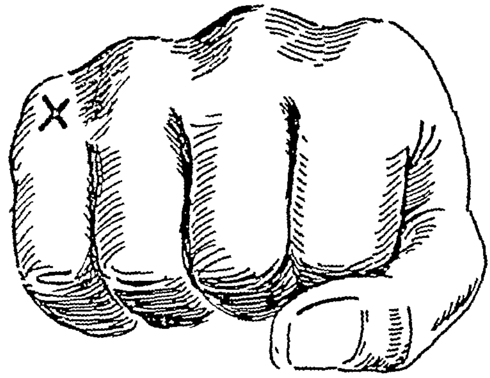

Fig 3—Most of head of metacarpal becomes subcutaneous with reduction of fracture Center of head is easily found and is point where pin should be introduced

Comment

Open fractures, which can be made clean in a few hours, can be pinned The bone, however, must be covered by skin Open fractures of the metacarpals are rare, and none has been encountered in this series Oblique, unstable fractures do not lend themselves well to this procedure and probably need traction for support

Observations

Several interesting side-lights on this procedure of intramedullary fixation have been found They are as follows

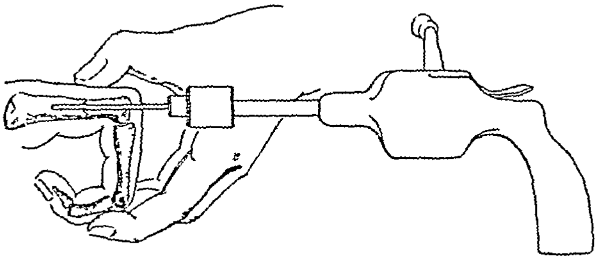

Fig 4—With forces necessary for reduction still being applied by an assistant, Kirschner wire is drilled into place

1 By burying the pin beneath the skin, no infection or weeping of any nature has been encountered Removal has been simple, because the pin was easily palpable subcutaneously It was removed with the patient under local anesthesia, in three to four weeks

2 Metacarpophalangeal joint motion has been limited while the pin was in place This was due to a mechanical block of the joint by the pin However, in all cases, motion returned to normal shortly after the pin was removed

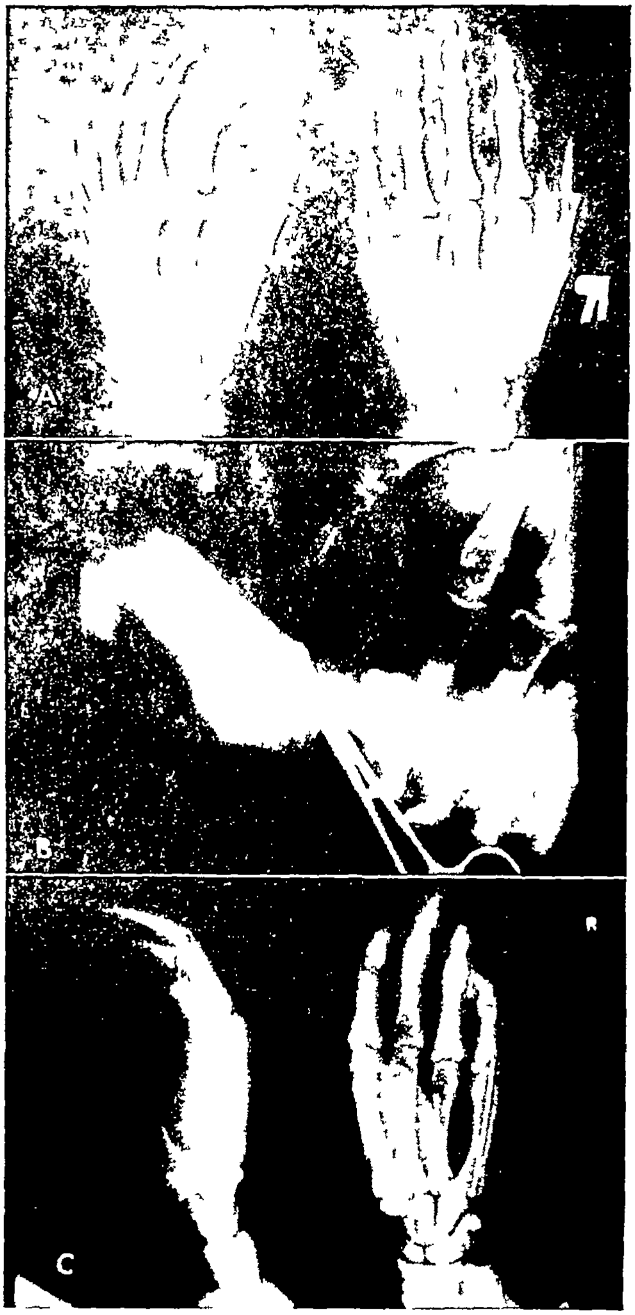

Fig 5—*A*, fracture of midshaft of fifth metacarpal *B*, x-ray taken in operating room Note pressure being applied to dorsal aspect of fracture to reduce it, counterpressure on flexed proximal interphalangeal joint is not shown, pin is introduced while this position is held *C*, reduced fracture with pin in place

3 In earlier cases of shaft fracture, no x-rays were made in the operating room In three procedures the pin missed the proximal fragment Nevertheless, stability was so good that no cast was applied Results were good and union occurred, with satisfactory alignment, in three to four weeks

4 Threaded wires were tried but were carded because of the difficulty of removal It was also felt that they did not increase the stability at the fracture site The unthreaded pins did not tend to migrate

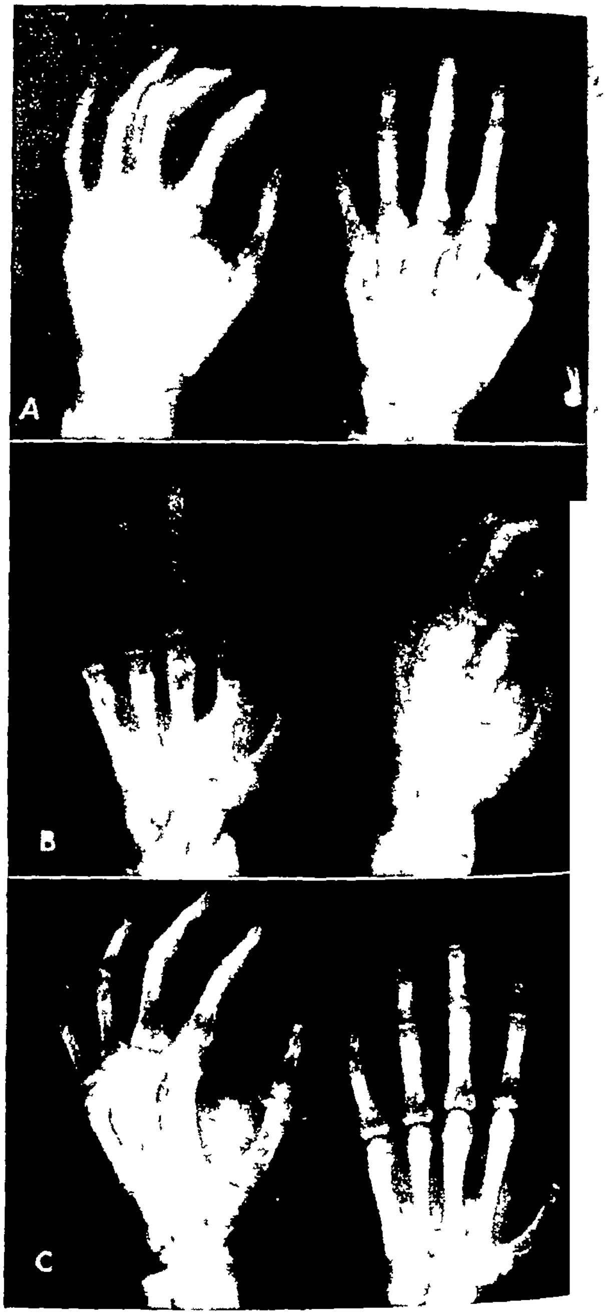

Fig 6—*A*, fracture of neck of fifth metacarpal (commo metacarpal fracture) *B*, reduction is anatomical and pin e gages carpometacarpal joint *C*, three weeks after fractur, p has been removed, fixation is excellent, and excessive callus h been avoided

5 Bony union has been solid enough in fresh frac tures in three weeks to remove the pins With fracture that occurred a week or more prior to pinning, the pin were left in place four weeks Solid unions have oc curred in both groups and no refractures have bee experienced

Summary

Thirty patients with metacarpal fractures have been treated by means of longitudinal intramedullary Kirschner wires with no external fixation Fixation has been good, union has been prompt, and no infection has been encountered As most of the fractures have been of the fifth metacarpal, it is felt that ulnar nerve block at the elbow has greatly simplified the procedure The fact that the patient is allowed to return to duty at once has pleased both the employer and the patient

EVALUATION OF DIATRIZOATE (HYPAQUE) IN PERIPHERAL ANGIOGRAPHY AND AORTOGRAPHY

Theodore B Massell, M D , S M Greenstone, M D
and
E Craig Herringman, M D , Los Angeles

• *There were no serious systemic effects after approximately 100 injections of diatrizoate salts for vascular opacification, administered to 83 patients Local reactions were infrequent and consisted of varying degrees of pain and vasospasm of very brief duration, although the vasospasm never led to ischemic symptoms, and there were no thromboses, even in the distal veins of the extremities No experimental studies have been performed to determine the possible effect on the spinal cord from large doses of diatrizoate, and it should not be assumed that massive doses of this product will not produce permanent paralysis when injected into the human aorta*

The roentgenographic delineation of arteries by injection of an opaque medium has been an established diagnostic procedure for many years–Recent developments in surgery of the blood vessels have greatly increased the importance and the use of angiography, with the result that many studies have been made to develop safer materials and improved techniques for their administration Generally, the substances which have been injected into the blood stream to opacify the vessels have been of two types About a decade ago a colloidal suspension of thorium dioxide (Thorotrast) was widely used in arteriography Because of the radioactivity of thorium and its indefinite retention in the body, it has been generally rejected for vascular opacification

More commonly today, the solutions of organic salts containing iodine are used Iodopyracet (Diodrast) and acetrizoate (Urokon) are the two preparations employed most frequently Iodopyracet has had extensive use in urography, and has been analyzed by Pendergrass and others [1] in mass surveys in 1942 and again in 1954 There were 57 deaths related to use of this material in almost 4,500,000 urographic examinations The majority of these deaths were apparently due to hypersensitivity to the drug, a condition which was not manifested by the usual sensitivity studies done prior to urographic examination Untoward reactions of a minor character, such as venous spasm, urticaria, angioneurotic edema, flushing, and pain, were quite common

With the increasing use of these substances in arteriography, various workers have noticed and reported serious reactions related to the mediums and technique of injection The neurosurgeons were among the first to note untoward reactions following cerebral angiography Perese and others [2] reported 37 complications with 35% iodopyracet in 234 carotid angiographic studies These consisted of 1 direct death, 6 deaths hastened by the examination, permanent hemiplegia in 3 cases, transient hemiplegia in 19 cases, sensory changes in 7 which were of transient nature, and 1 retinal artery occlusion Sutherland and others [3] employed a 25% solution of iodopyracet instead of the usual 35%, and, while obtaining satisfactory cerebral angiograms, noted only 2% complications instead of 16% with the higher concentration

The utilization of these substances in peripheral angiography and aortography has been associated with occasional serious reactions There have been reported several instances of both partial and permanent paraplegia and death following the use of acetrizoate in aortography [4] Other complications have been arterial thromboses of visceral vessels resulting in necrosis and death [5] and also cases of renal shutdown [6]

Recent experimental work has shed some light on the mechanism of these reactions Foltz, Thomas, and Ward [7] demonstrated a direct toxic action of iodopyracet on brain nerve cells of the monkey The same substance injected into the aortas of rabbits produced increased permeability of cord vessels and spinal cord damage [8] Bloor, Wrenn, and Margolis [9] showed similar changes in vascular permeability and progressive edema in the monkey brain after injecting 50-75% iodopyracet Recently Tarazi, Margolis, and Grimson [10] reported the experimental production of spinal cord

---

Read before the eighth International Congress of Radiology, Mexico City, July 25, 1956 lesions in dogs, using equal amounts of 70% iodopyracet and 70% acetrizoate The lesions were mainly in the gray matter, were less marked in the white matter, but approached complete transection in some cases The incidence of severe cord damage was higher with acetrizoate than with iodopyracet, apparently due to the higher iodine concentration in the former Thomson and co-workers [10] have also produced massive renal destruction by injecting the same mediums directly into one renal artery

As a result of such experiences, the development of safer contrast materials has been stimulated Early in 1955 we undertook a clinical study of the salts of diatrizoate (Hypaque) as opacification mediums in angiography Favorable reports had already appeared regarding the use of a 50% solution of the sodium salt in intravenous urography Bodner, Howard, and Kaplan [11] reported its use in 300 cases of intravenous urography and noted a higher percentage of diagnostic contrast in the x-ray films and a greatly decreased incidence of undesirable side-effects as compared to acetrizoate, iodopyracet, and iodomethamate (Neo-Iopax) These observations have been substantiated by Engelhardt and Jacobson [12] and by Lentino and others [13] The latter have also reported favorable experiences with Renografin, a mixture of the sodium and methylglucamine salts of diatrizoate Our studies are concerned with the sodium salt of diatrizoate and also a mixture of the methylglucamine and sodium salts in the proportion of 2 to 1 Eighty-three patients were studied 42 for phlebography, 28 for peripheral arteriography, and 13 for aortography

Untoward Reactions with Different Contrast Mediums Used for Phlebography

	Total No of Limbs	Systemic Reactions		Local Pain and Spasm			Total No of Untoward Reactions
		Nausea	Urticaria	Slight	Moderate	Severe	
Sodium salt of diatrizoate	27	1	1*	2	7	4	15
Methylglucamine and sodium salts of diatrizoate	23	1		5	1	1	8
Iodopyracet (controls)	2	2		1			8

* An additional patient developed urticaria after a test dose Phlebography was not performed

Phlebography

All the injections for the phlebograms were made precutaneously into a distal vein of an extremity Fifty-two limbs were injected 27 with the sodium salt of diatrizoate, 23 with a mixture of sodium and methylglucamine salts, and 2 with iodophyracet Most of the solutions were made in a 35% concentration for the lower extremities, although a 50% solution was used in the upper extremities At first, for all cases in which bilateral phlebography was to be performed, it was planned to use iodopyracet in one extremity and diatrizoate in the other After the first two cases, however, it seemed unjust to subject patients to the well-recognized distressing systemic effects of iodopyracet The table shows the incidence of untoward reactions

The opacification of the veins seemed generally more intense with diatrizoate or the combined salts than that to which we had previously been accustomed with iodopyracet (fig 1) With the use of the sodium 27 limbs, the results were excellent in 10 cases, good in 15, and unsatisfactory in 2 With the use of the methylglucamine and sodium salts in 23 limbs, results were excellent in 13 cases, good in 8, and unsatisfactory in 2 All four cases listed as unsatisfactory actually involved technical errors, so that the medium was not at fault In the others, a reasonably uniform technique was employed throughout Despite the small number of cases in this series, there appeared to be a significant difference between results with the mixed salts, which showed excellent intensity in 62%, as compared to those with the sodium salt alone, which showed excellent intensity in only 37%

Peripheral Arteriography

Peripheral arteriography was performed in 28 cases, none with use of general or spinal anesthesia All were performed by injection of the medium into the femoral artery, and, since more than one injection was used in some cases in order to demonstrate additional areas, 36 injections were performed in all In two cases the artery was exposed surgically, in the others a percutaneous route was used The sodium salt was employed 22 times, and the mixture of methylglucamine and sodium salts 14 times In all cases a 50% sc was used The dosage varied from 6 to 15 cc, depending on the nature and location of the lesion and the size of the patient There were no systemic reactions Approximately 45% of the patients complained of pain or burning in the injected leg after the sodium salt was used for arteriography In four these instances the pain was associated with tary motion The opacification was satisfactory every case but was considered excellent in 73% the sodium salt and 86% with the mixture (fig 2)

Aortography

Only 13 patients underwent aortography, and in of these cases injections were given by the bar route with no anesthesia other than local in tion of the skin with procaine A 50% solution of sodium salt was tried in the first four cases, but opacification was so poor that its use was dis A 90% solution of the mixture of methylglucamine sodium salts was then used At room temperature contains a precipitate which goes into solution the preparation is warmed to body temperature concentrated solution, however, is so viscous that with the ordinary injection technique, using a 17-gauge thin-walled needle, it was impossible to inject rapidly enough to achieve satisfactory opacification We also had the impression that the filling of the collateral channels was poor with this 90% solution, possibly because of the viscosity In the last five cases we used a 70% solution of the mixed salts

Between 20 and 30 cc was easily injected, so that the viscosity was not too much of a problem and the opacification was fairly satisfactory The most striking thing in these cases was the complete absence of any discomfort, and none of the patients seemed even aware that the contrast medium had been injected There were no systemic reactions

Comment

Toxicity studies[14] have been performed in the dog and rabbit to compare diatrizoate with acetrizoate. The dosage level required to produce death in the dog, using acetrizoate, was 6,300 mg per kilogram of body weight and in the rabbit, 5,200 mg per kilogram With diatrizoate the dosage levels necessary for death were 13,200 mg and 12,200 mg per kilogram respectively Diatrizoate thus appears to be approximately half as toxic as acetrizoate in the dog and rabbit Blood-brain barrier studies in the rabbit[14] revealed very slight evidence of extravasation with diatrizoate, both in the form of pure sodium salt and in the mixture of the methylglucamine and sodium salts, as compared to iodopyracet and acetrizoate, both of which produced marked evidence of extravasation As yet, no experimental studies to determine the possible effect on the spinal cord from large doses of diatrizoate have been performed Until special studies are done, such as those made by Tarazi, Margolis, and Grimson[9c] with acetrizoate, it should not be assumed that diatrizoate will not produce permanent paralysis when injected into the human aorta Furthermore, Thomson and co-workers[10] found that diatrizoate was only slightly less toxic than iodonyracet and acetrizoate when injected directly into the renal artery

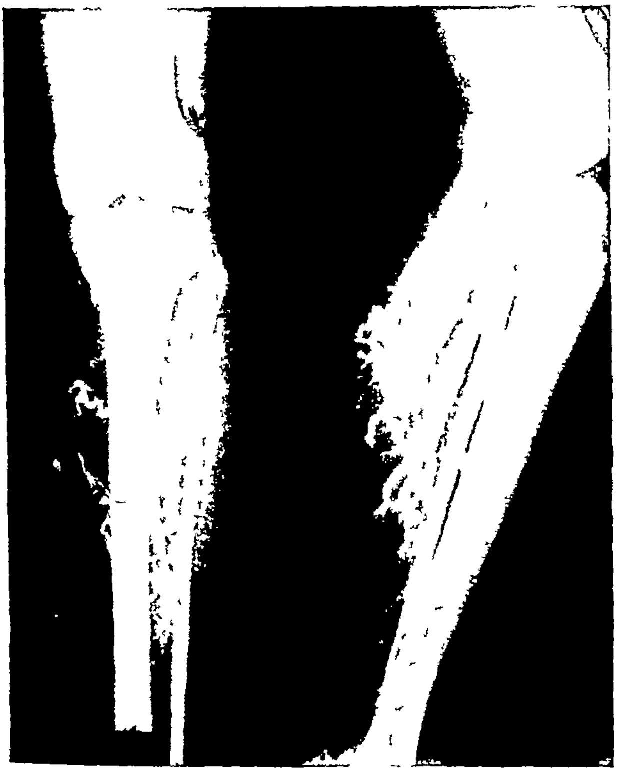

Fig 1—Phlebogram made with mixture of methylglucamine and sodium salts of diatrizoate Communicating and perforating veins are well delineated, as is deep venous system

In this preliminary study, there were no serious systemic effects after approximately 100 injections of diatrizoate salts for vascular opacification The only untoward general reactions were mild and few two transient episodes of nausea not associated with vomiting and one case of urticaria Local reactions were more frequent and consisted of varying degrees of pain and vasospasm of very brief duration This reaction was present only after the injection of the medium into smaller vessels and was completely absent after intra-aortic injections The pain was never severe enough to be intolerable and only rarely caused motion which interfered with the obtaining of a clear roentgenogram The vasospasm never led to ischemic symptoms, and there were no thromboses, even in the distal veins of the extremities

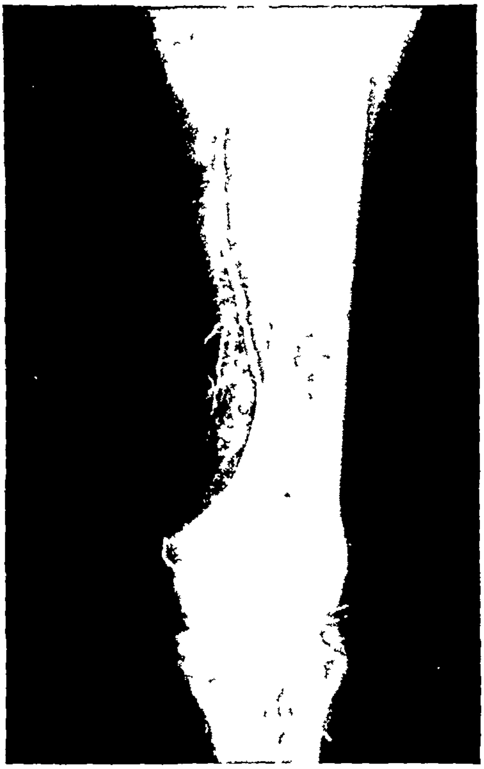

Fig 2—Femoral arteriogram made with mixture of salts of diatrizoate Although lumen of the popliteal artery is almost thread-like in size, it is still clearly visible along with fine collateral channels

Conclusions

When used for the roentgenographic opacification of blood vessels, diatrizoate (Hypaque) produces considerably fewer untoward general and local reactions than the other commonly used organic iodine compounds The mixture of the methylglucamine and sodium salts of diatrizoate appears to be better tolerated and to give more intense opacification than the sodium salt alone Further experimental work is indicated to determine possible direct toxic effects on spinal cord and renal tissues

6317 Wilshire Blvd (48) (Dr Massell)

The diatrizoate salts used in this study were supplied by Winthrop Stearns, Inc, New York

CLINICAL NOTES

ORAL CHOLANGIOGRAPHY

PRELIMINARY REPORT

Michael J Stamatakos, M D
and
Kenneth W Taber, M D, Allentown, Pa

Roentgenographic visualization of the bile ducts [illegible] oral administration of iopanoic acid (Telepaque) in patients with functioning gallbladders has been mentioned by nearly all authors reporting their experiences with this contrast material, but we have been unable to find any report in the American literature regarding such visualization in patients with nonfunctioning gallbladders We have frequently visualized the hepatic and common bile ducts 12 hours after the oral administration of iopanoic acid in patients whose gallbladders were not visualized, and, in several of these patients, as in the patient in case 58, the cystic duct was also clearly seen (fig 1) Heretofore such visualization of the ducts after oral administration of iopanoic acid had been ignored or interpreted as "contrast material" in the alimentary canal, as, for example, in the duodenum It is, therefore, the purpose of this report to present some of our experiences with oral cholangiography in order to place this method among the biliary diagnostic techniques

Although a great majority of nonvisualized gallbladders are considered pathological, clinicians occasionally find difficulty in determining whether nonvisualization of the gallbladder is due to pathology in this organ or to impaired excretory function of the liver The differential diagnosis then becomes important, because surgery is contraindicated in liver disease This differential can be made by oral cholangiography

The oral cholangiogram of the patient in figure 2 (case 59) is an example of this fact A stone obstructing the cystic duct was mentioned in the x ray report of this patient before operation, when the physician was about to treat him for hepatitis, and was found at surgery We gave this preoperative opinion because of the concentration of the 'dye' in the common duct with nonvisualization of the gallbladder

Oral cholangiography is so much safer, cheaper, and easier than the intravenous method that we prefer to use it first The intravenous technique may be used to establish more clearly the presence of a stone in the common duct subsequent to the oral technique, as was done in the patient in case 46, whose cholangiograms are shown in figure 3 and in whom the stone was subsequently removed from the common duct at operation

The cholangiogram in figure 4A (case 14) shows the visualization of the common duct by the oral technique An intravenous pyelogram is presented on this same patient in order to show that the internal structures of the right kidney could not have been interpreted as biliary radicles by this method Figure 5 (case 39) shows, for comparison, the common ducts as visualized by both oral and direct 'T-tube'

Third-year resident in radiology (Dr Stamatakos) and Director, Department of Diagnostic Roentgenology (Dr Taber) ared Heart Hospital

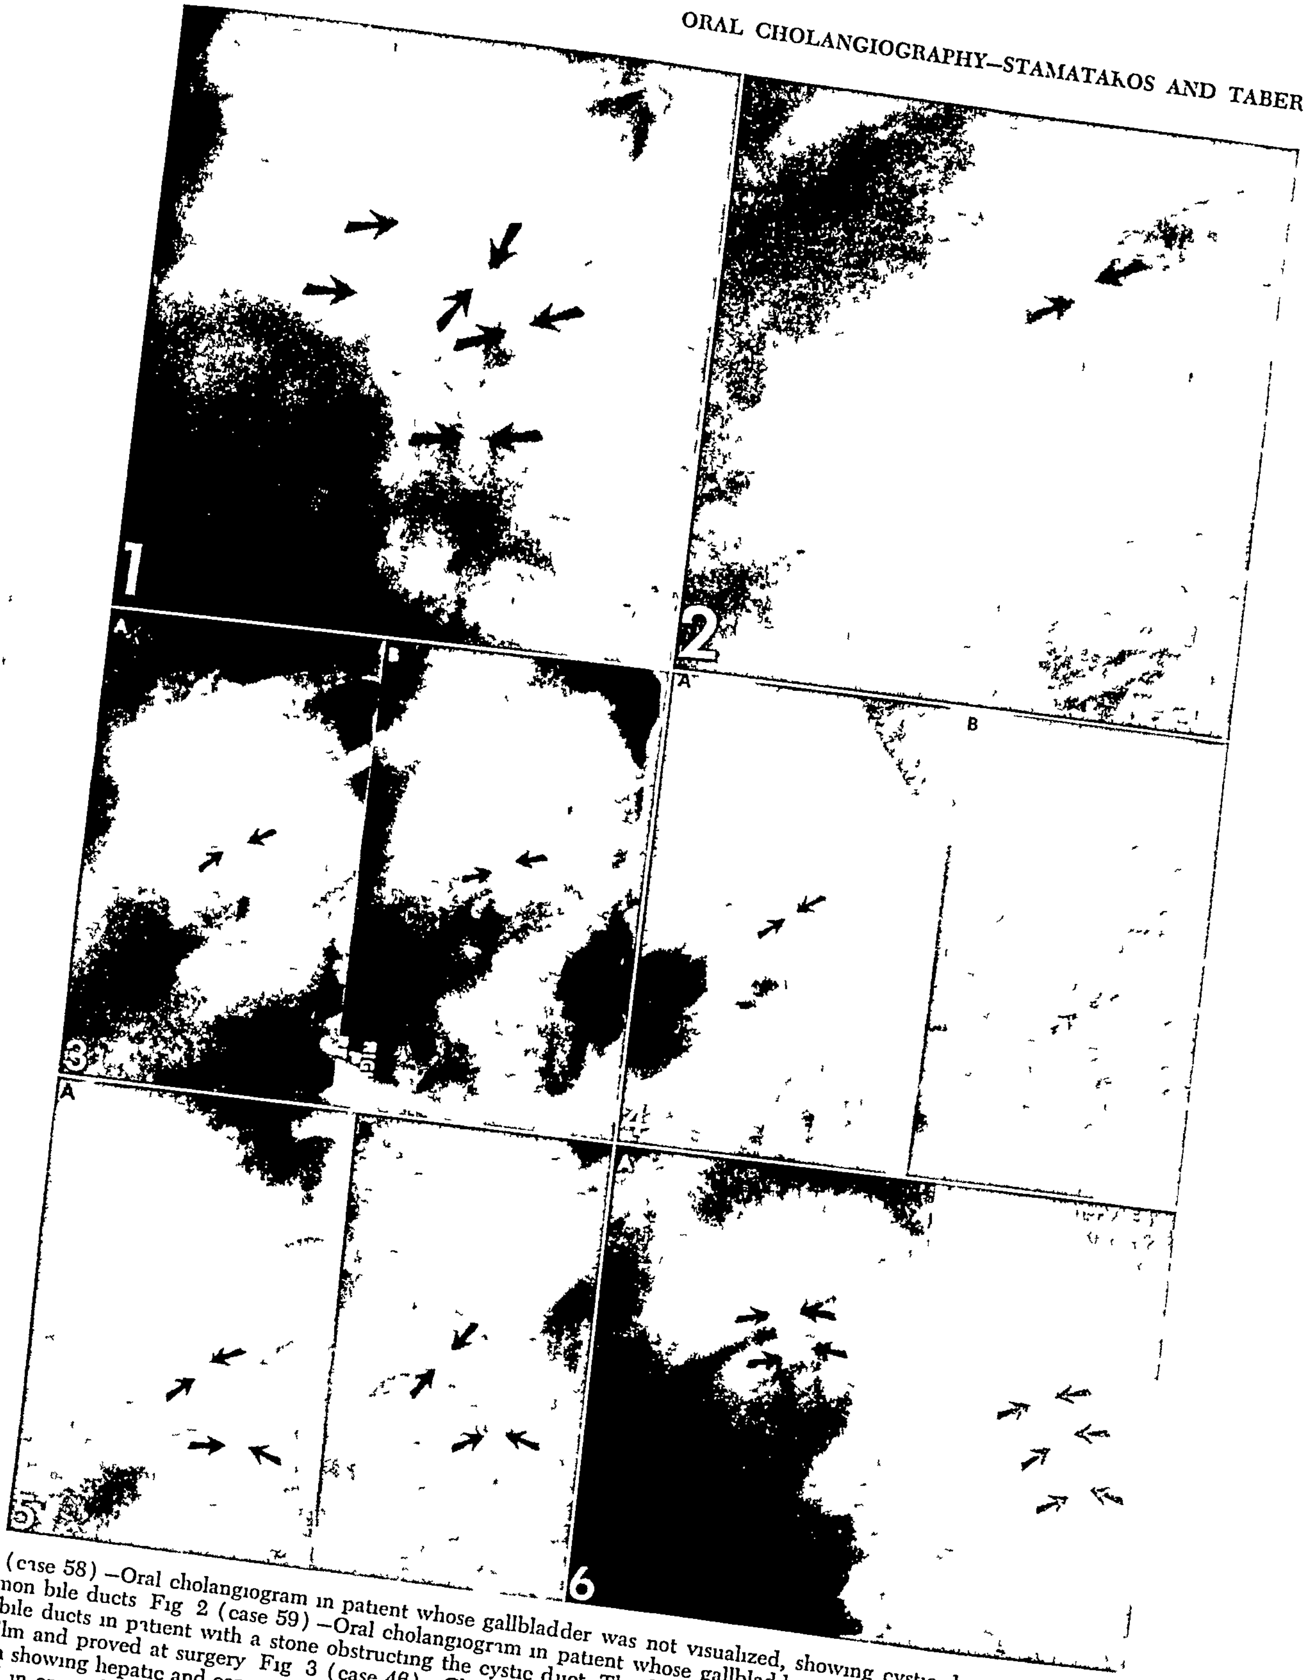

Fig 1 (case 58)—Oral cholangiogram in patient whose gallbladder was not visualized, showing cystic duct in addition to hepatic and common bile ducts Fig 2 (case 59)—Oral cholangiogram in patient whose gallbladder was not visualized, showing hepatic and common bile ducts in patient with a stone obstructing the cystic duct This had been reported preoperatively on the basis of this one 12 hour film and proved at surgery Fig 3 (case 46)—Cholangiograms in patient whose gallbladder was not visualized A oral cholangiogram showing hepatic and common bile ducts B, intravenous cholangiogram on same patient to verify common bile duct calculus mentioned in original report on A Fig 4 (case 14)—A, oral cholangiogram showing biliary tree B intravenous pyelogram of right kidney of same patient for comparison, to show that the internal structures of the kidney could not have been interpreted as biliary radicles by this method Fig 5 (case 39)—A oral cholangiogram showing biliary radicles B direct T-tube cholangiogram on the same patient for comparison Fig 6 (case 30)—A, oral cholangiogram showing biliary radicles B intravenous cholangiogram on the same patient for comparison

* Patient not examined for clinical evidence of disease of liver or common duct

cholangiography Figure 6 (case 30) also shows the bile ducts as visualized by both oral and intravenous techniques for comparison

Material and Methods

The only patients included in this study are those whose gallbladders had not been removed and whose gallbladders could not be visualized even with "reinforcement' Reinforcement consisted of administration of iopanoic acid a second time 12 hours after the first examination and examination of the patient 12 hours after this, or 24 hours after the first examination, with the patient remaining on a fat-free diet all the while If the gallbladder was faintly visualized at any time, the patient was excluded from the study The usual routine for oral cholecystography was followed, including reinforcement for a second day in all cases in which the gallbladder was not visualized the first day

Results

Of the 724 most recent cholecystograms, 67 (9 2%) failed to demonstrate iopanoic acid in the gallbladders of patients who had not had that organ removed These 67 cases constitute the present study group (see table) Forty-eight (71 4%) of the 67 patients with nonvisualized gallbladders showed iopanoic acid in the common bile duct Neither the gallbladder nor the common bile duct was visualized in 19 patients (28 6%), but in only 4 of these 19 patients was this nonvisualization not explained by clinical evidence of liver or common duct disease Three of the four patients were not examined for such evidence, in the fourth, complete pyloric obstruction explained this nonvisualization We are unable to explain why the common duct was visualized in two of the patients with clinical evidence of liver disease These findings suggest to us that the hepatic and common bile ducts take over the concentrating function of the gallbladder when that organ is not functioning

Summary and Conclusions

Seven hundred twenty-four oral cholecystograms were made, with iopanoic acid (Telepaque) used as the contrast medium, in patients who had not had their gallbladders removed In every patient with nonvisualization of the gallbladder, either the common bile duct was demonstrable or the patient had clinical evidence of liver or common bile duct disease, with four possible exceptions In one such exception there was complete pyloric obstruction, and the other three patients were not examined for clinical evidence of liver or common duct disease These findings indicate that, with a careful examination, the common duct can be visualized in patients with gallbladder disease provided they do not have malfunctioning livers or common bile ducts Also, with the perfection of this technique, a new diagnostic tool can be added to gastrointestinal studies

COUNCIL ON DRUGS

Formerly the Council on Pharmacy and Chemistry

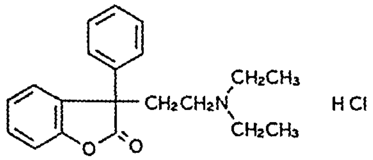
NEW AND NONOFFICIAL DRUGS

Formerly New and Nonofficial Remedies

Monographs and supplemental statements on drugs described here and in subsequent editions of New and Nonofficial Drugs are based on the evaluation of available scientific data and reports of investigations Applicable commercial names for preparations of evaluated drugs are listed at the end of monographs and parenthetically in the text of supplemental statements, additional commercial names of which the Council is informed will be included with subsequently published supplemental statements and annual editions of New and Nonofficial Drugs

H D Kautz, M D, *Secretary*

Amolanone Hydrochloride —3-(β-Diethylaminoethyl) -3-phenyl-2-benzofuranone hydrochloride —The structural formula of amolanone hydrochloride may be represented as follows



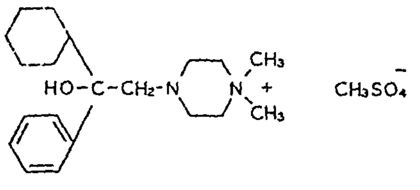
Actions and Uses —Amolanone hydrochloride is a benzofuranone derivative with both anticholinergic and local anesthetic actions The drug formerly was used as an intramuscularly administered antispasmodic for the relief of ureteral colic due to calculi, spasm, and instrumentation, a purpose for which it has been withdrawn Its clinical use is now confined exclusively to topical anesthesia of the lower urinary tract When it is instilled into the urethra, anesthetic effects are stated to become apparent within 5 minutes and to persist for 15 to 30 minutes Accordingly, the drug is proposed for the production of topical anesthesia prior to carrying out such urologic procedures as catheterization, urethral dilatation, cystoscopy, and panendoscopy It is also proposed for the relief of pain in such conditions as interstitial cystitis with ulceration (Hunner's ulcer) However, because some investigators report unsatisfactory results with this agent, it is difficult to define with certainty the real usefulness of amolanone hydrochloride as a topical anesthetic Some urologists indicate that the drug is equal or superior to butacaine and procaine, a minority has been unable to produce satisfactory anesthesia Hence, the ultimate usefulness of this drug as a local anesthetic must await the results of further clinical experience

On the basis of prior experience with the drug as a systemic spasmolytic and more recent reports on its use as a topical anesthetic, amolanone hydrochloride may be described as a drug of low toxicity After intraurethral instillation, *only* isolated instances of slight giddiness, a transitory burning sensation, or mild dizziness have been reported There is no evidence that appreciable quantities of the drug are absorbed from the urethral mucosa, and it has been used in patients with lower urinary tract bleeding without untoward effects In view of its apparently low order of toxicity and the favorable reports so far recorded, further careful trial of the local anesthetic action of this drug is indicated

Dosage —Amolanone hydrochloride is employed as a 0 33% solution (3 3 mg per cubic centimeter) for intraurethral instillation prior to *performing* urologic procedures This solution should not be injected into the tissues The urethra is filled with the solution, and the meatus is closed with a penile clamp After three to five minutes, the clamp is removed and the procedure begun

Applicable commercial name Amethone Hydrochloride
Abbott Laboratories cooperated by furnishing scientific data and in the evaluation of amolanone hydrochloride

Hexocyclium Methylsulfate —N-(*β*-Cyclohexyl-*β*-hydroxy-*β*-phenylethyl)-N′-methylpiperazine dimethylsulfate —The structural formula of hexocyclium methylsulfate may be represented as follows



Actions and Uses —Hexocyclium methylsulfate, a synthetic anticholinergic quaternary ammonium compound, is chemically related to certain other drugs of this class and is qualitatively similar to these drugs in pharmacological action After therapeutic doses have been administered, the autonomic blocking effects of hexocyclium methylsulfate are limited to effector cells innervated by postganglionic cholinergic nerves At sufficient doses, in animal experiments, the drug inhibits gastrointestinal motility and spasm, diminishes gastric secretion, dilates the pupil, inhibits salivation, relaxes the musculature of the bladder, and counteracts the muscarinic effect of choline esters In these respects, its principal pharmacological actions as well as side-effects may therefore be described as atropine-like On a weight basis, the drug is less potent than atropine in vitro but is more potent by a number of tests in vivo In large doses in animals, hexocyclium methylsulfate (and other compounds of its class) produces ganglionic blockade and curare-like effects interfering with neuromuscular transmission The metabolic fate and excretion of hexocyclium methylsulfate are not known The drug is readily absorbed from the gastrointestinal tract Its onset of action is prompt, and, after ordinary doses, anticholinergic effects persist about three to four hours No apparent cumulative toxic effect in animals has been observed after prolonged administration of large daily doses

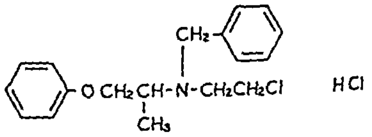
Hexocyclium methylsulfate may be used for the adjunctive management of peptic ulcer and other gastrointestinal disorders associated with hyperacidity, hypermotility, and spasm in which anticholinergic action might be considered beneficial The antisecretory response to a fixed dose of hexocyclium methylsulfate appears to be variable In some patients, gastric secretion is reduced to the point of anacidity, in others, the response is less marked or is minimal The latter might be attributed to insufficient dosage For the control of functional disorders of the gastrointestinal tract, especially peptic ulcer, hexocyclium methylsulfate should not be employed to the exclusion of dietary restriction and the use of antacids and sedatives In certain cases, these measures may be more important in the therapeutic regimen than anticholinergic drugs In some cases, anticholinergic drugs are not indicated or are without benefit Although hexocyclium methylsulfate effectively allays hypermotility and hyperacidity, there is no evidence that it possesses greater therapeutic effectiveness than certain other drugs of this class

Side-effects associated with hexocyclium methylsulfate are those of anticholinergic drugs in general Dryness of the mouth (xerostomia) may be encountered when therapeutically effective doses are administered, but it is often transient and is usually mild Likewise, blurring of vision, difficulty in urination, and palpitation may occur but usually only with excessive doses Side-effects can often be minimized by adjustment of dosage As with any new drug, until more experience is gained, physicians should be alert to the possible development of serious untoward effects that may result from continued use of the drug

Dosage —The suggested initial dosage for adults is 25 mg four times daily, administered orally, preferably before meals and at bedtime The maintenance dosage of hexocyclium methylsulfate should be arrived at by careful adjustment to the needs and tolerance of the individual patient

Applicable commercial name Tral
Abbott Laboratories cooperated by furnishing scientific data to aid in the evaluation of hexocyclium methylsulfate

Phenoxybenzamine Hydrochloride — N-(2 Chloroethyl)-N-(1-methyl-2-phenoxyethyl)benzylamine hydrochloride —The structural formula of phenoxybenzamine hydrochloride may be represented as follows



Actions and Uses —Phenoxybenzamine hydrochloride is a potent adrenergic blocking agent of the *β* haloalkylamine series The pharmacology of this drug and that of its closely related congener, dibenzyl-β-chlorethylamine (Dibenamine), have been carefully studied. The drug selectively blocks the excitatory response of smooth muscle and exocrine glands to epinephrine but does not abolish the inhibitory response of smooth muscle or the myocardium to epinephrine-like agents. Thus, adrenergic blockade with phenoxybenzamine has been compared to "chemical sympathectomy." As with all agents in this category, phenoxybenzamine blocks the response to endogenous or exogenous epinephrine more effectively than it blocks the response to adrenergic nerve stimulation. Hence, the separation of adrenergic blocking agents into adrenolytic and sympatholytic drugs is now believed to be largely artificial, although phenoxybenzamine would ordinarily be considered a representative of the former. The drug reduces or abolishes the pressor response not only to epinephrine but to other sympathomimetic amines as well; in experimental animals, adrenergic blockade with phenoxybenzamine protects against doses of epinephrine that would ordinarily be supralethal. Before adrenergic blockade has been completed, the effects of the drug can be overcome by large doses of epinephrine. Once full blockade has been produced, however, neither epinephrine nor any other drug now known will break through it, and this blocking action is persistent. The precise site of adrenergic blockade with phenoxybenzamine has been accurately pinpointed. Studies have shown conclusively that the drug does not alter or block the release of adrenergic mediator, influence thoracolumbar (sympathetic) outflow or spinal reflex arcs, cause sympathetic ganglionic blockade, nor alter the ability of smooth muscle to contract to nonsympathomimetic musculotropic stimuli. Hence, the drug acts directly and specifically on adrenergic receptor cells in a noncompetitive manner in such a way that the receptiveness to adrenergic (sympathomimetic) stimuli is decreased or abolished.

Although phenoxybenzamine hydrochloride is sparingly soluble in water, at least 20 to 30% of an orally administered dose is absorbed in an active form from the gastrointestinal tract. The duration of action of the drug is prolonged; after a single full dose, adrenergic blockade persists for three to four days or longer. Approximately 50% of the drug appears in the urine and bile within 12 hours after oral administration.

Except for a mild antihistaminic action and moderate miosis, the effects of the drug are predominately those of peripheral vasodilation. Thus, increases in peripheral blood flow and skin temperature and a lowering of blood pressure in patients in both supine and erect positions are the outstanding effects of adrenergic blockade with this agent. The drug also suppresses the hyperglycemic response to epinephrine and blocks epinephrine-induced discharge of corticotropin. The ancillary actions of phenoxybenzamine are minimal; it has no effect on the parasympathetic system and produces only negligible changes in gastrointestinal tone and motility.

Phenoxybenzamine and related β-haloalkylamines previously were considered interesting and valuable laboratory tools for pharmacological research but of little clinical usefulness. However, with the elucidation of the discrete adrenergic blocking properties of these compounds, it became apparent that they might prove useful for the treatment of certain peripheral vascular diseases. Subsequent clinical trials have confirmed not only their efficacy for this purpose but also the superiority of phenoxybenzamine hydrochloride over other chemically related compounds in the series. As might be expected from its pharmacological actions, phenoxybenzamine is more effective in those peripheral vascular diseases characterized by excessive vasospasm than in those of the organic occlusive forms. Thus, the drug is of value in such conditions as Raynaud's syndrome, acrocyanosis, causalgia, chronic vasospastic ulceration of extremities, and frostbite sequelae; it may also be of value in those forms of obliterative or obstructive arterial disease that are complicated by vasospasm of vessels remaining patent. Because of its specificity, effectiveness when given orally, and prolonged action, it is considered preferable to other available adrenergic blocking agents for the medical management of these conditions. If sufficient time is allowed for full adrenergic blockade to develop, a large percentage of patients with vasospastic involvement may be expected to show objective and subjective improvement including relief of causalgic pain, healing of lesions, clearing of cyanosis or ischemia, and increase in skin temperature. The drug is considered by some authorities to be superior to cervical sympathectomy for most cases of bilateral digital ischemia of the upper extremities, and its therapeutic trial is indicated in cases of severe causalgia before sympathectomy is performed. In patients hospitalized for acute peripheral vascular accidents, phenoxybenzamine also appears to be useful to combat reflex spasm of collateral vessels and of the originally occluded vessel after embolectomy. It has been administered to patients with such conditions as thromboangiitis obliterans (Buerger's disease) and intermittent claudication, but the results have been only fair.

Phenoxybenzamine hydrochloride has been employed for the management of moderate to severe hypertension. Although high doses undoubtedly lower blood pressure, clinical experience has indicated that excessive postural hypotension and other undesirable effects usually outweigh the benefits attained. Hence, the drug is no longer considered useful for this purpose when employed alone. It has, however, been combined in small amounts with the alkaloids of Rauwolfia and Veratrum for the management of hypertension. Other experimental uses of the drug have included the treatment of toxemia of pregnancy, cardiospasm, glaucoma, and the preoperative management of pheochromocytoma. At present there is insufficient evidence to justify the use of the drug in any of these conditions. Since phenoxybenzamine blocks the excitatory but not the inhibitory response of smooth muscle to epinephrine, it has been employed intravenously in patients with status asthmaticus to permit the safer administration of exceedingly large doses of epinephrine. While this is a logical clinical application of the drug's pharmacological actions, this use should at present be considered experimental.

Most of the side-effects of phenoxybenzamine result from the ability of the drug to produce adrenergic blockade and may be considered for the most part extensions of the therapeutic action The side-effects most commonly encountered are nasal congestion, miosis, tachycardia, and postural hypotension Occasionally, sedation and drowsiness occur, and male patients sometimes experience failure of ejaculation Since the drug blocks salivation in those glands innervated by sympathetic fibers, some degree of xerostomia may occur The drug produces little, if any, gastric distress, nausea, or vomiting Most side-effects tend to decrease as therapy is continued The development of some tolerance after prolonged therapy is likely, although complete refractoriness to the drug is rare

Phenoxybenzamine is contraindicated in any condition in which a fall in blood pressure may be undesirable or dangerous It should be given with extreme caution to hypertensive patients with cerebral atherosclerosis or renal damage In patients with compensated congestive heart failure or coronary artery disease, the tachycardia that sometimes accompanies high doses may precipitate frank failure and anginal attacks Adverse hematopoietic effects from phenoxybenzamine have not been reported in either laboratory studies or clinical use

Dosage —Phenoxybenzamine hydrochloride is administered orally Dosage is variable and must be individualized according to the therapeutic response and the appearance of side-effects As a general guide, 10 to 20 mg once daily may be given to initiate therapy After four days at this dosage, the daily amount is increased by 10 mg and thereafter increased by similar increments until a satisfactory response is obtained The usual maintenance dosage ranges from 20 to 60 mg once or twice daily In some patients, particularly those in whom hypertension is present, dosages of 0 2 Gm or more per day may be necessary At least two weeks or more are required before full adrenergic blockade develops and maximal therapeutic results are obtained

Applicable commercial name Dibenzyline

Smith, Kline & French Laboratories cooperated by furnishing scientific data to aid in the evaluation of phenoxybenzamine hydrochloride

COUNCIL ON FOODS AND NUTRITION

Report to the Council

The following paper was presented at the symposium, 'The Relation of Proteins and Amino Acids to Human Nutrition," in Los Angeles, May 21, 1956 This symposium was sponsored by the Council on Foods and Nutrition, with the cooperation of the Los Angeles County Medical Society and the School of Medicine, University of California at Los Angeles This report is the sixth and final report of this series, which will be available in monograph form

Philip L White, Sc D , *Secretary*

ROLE OF HORMONES IN PROTEIN METABOLISM

Robert E Olson, M D , Ph D , Pittsburgh

Despite the large volume of research that has been published in the field of endocrinology during the past 50 years, the precise biochemical function of a hormone has yet to be established It is clear, however, that several hormones influence protein metabolism in such a way as to produce effects of considerable interest to the clinician as well as to the biochemist The purpose of this presentation will be to consider both the clinical and biochemical implications of the hormonal adjustments in a number of common medical situations

The object of endocrine control might be stated to be an adjustment of metabolism through the intervention of numerous hormones acting in specific biochemical or biophysical areas to produce optimum substrate concentrations, adequate enzyme activity, and appropriate work performance in all organs and tissues in a variety of physiological and pathological states In some instances, two hormones may stimulate a single process in different directions Such an arrangement lends balance to homeostasis, increases the inertia of the organism, and makes for more stability under changing metabolic conditions

Because of its supercatalytic function in metabolism, the biological activity of hormones is influenced by many other parameters such as genetic strain, sex, age, diet, activity, emotionality, bacterial flora, physical environment, dosage, and time of observation In certain biological responses, Ingle[1] has demonstrated that the hormones may play only a permissive role, making possible but not being solely responsible for the given response

The role of the hormones in protein metabolism is considered herein in connection with five clinical situations that involve imbalance of endocrine secretions under physiological or pathological conditions The physician who is constantly faced with these problems must judge the endocrine changes per se and the relative contribution of many of the parameters such as diet, age, heredity, infections, or inflammation that are important in influencing the final clinical

---

From the Department of Biochemistry and Nutrition, Graduate School of Public Health, University of Pittsburgh

picture The role of diet therapy in specific situations and its relationship to the endocrine aspects of each case will be discussed

Growth

Childhood and adolescence afford unusual opportunities for study of the effects of various hormones In adults, hormonal dysfunction is manifested largely by unseen metabolic and physiological disturbances, as is the case with nutritional disorders in the adult, with the exception of frank deficiency disease In childhood or adolescence, these same metabolic disorders involving nutrition and hormonal secretion may alter growth and differentiation of tissues and cause a marked deviation from the usual patterns of somatic growth and development

Normal growth depends upon many factors, including genetic control, endocrine control, and nutritional status Furthermore, normal digestion, absorption, and circulation must be present in order to guarantee the delivery of nutrients to their locus of action Normal kidney function is essential for the maintenance of an optimum internal environment for the occurrence of anabolic reactions Therefore, growth failure may result from a wide variety of factors, including inborn errors of metabolism, endocrine insufficiency, nutritional deficiency, and breakdown in the function of any of the major organ systems

The following hormones are known to be concerned with the processes of growth the growth hormone of the anterior pituitary, estrogens, testosterone and other androgens, insulin, and thyroxin and other thyroid hormones All of them promote the storage of nitrogen as tissue protein and thus stimulate a positive nitrogen balance under optimum conditions None of these hormones alone is sufficient for normal growth, and all are thought to have dissimilar modes of action

Pituitary growth hormone is chiefly responsible for growth in the years prior to puberty In these years, there is a high serum phosphorus level, an increased plasma growth hormone level, and no epiphysial closure In the absence of pituitary growth hormone, pituitary dwarfism occurs Thyroxin and insulin are also required for growth in this period, if either is absent, dwarfism also occurs At birth, the ratio of upper to lower skeletal segments is 1 7 1 0, at age 10 years, it is 1 1 A hypothyroid dwarf (cretin) who has the height of a 2-year-old retains infantile proportions, that is, a ratio of upper to lower skeletal segments of 1 5 1 0 [2] Dwarfs produced by diabetes or a lack of pituitary growth hormone develop more mature proportions, although their total height is reduced Since the thyroid hormone is important in differentiation as well as in growth, hormonal therapy of cretins is of the utmost importance in order to preserve normal development as well as growth

Just prior to the onset of puberty, pituitary gonadotropins are elaborated They stimulate the gonads to secrete their characteristic steroid hormones that stimulate the growth of both bone and soft tissue Testosterone and other androgens cause growth of both bone and soft tissue, maturation of the skeleton, and closure of the epiphyses The main metabolic effect of estrogens, on the other hand, is the stimulation of bone anabolism through retention of calcium and phosphorus In the male, the gonads secrete androgens, and the adrenal cortex secretes small amounts of estrogens In the female, whose gonads secrete estrogens, the pubertal growth spurt and skeletal maturation are caused by elaboration of an anabolic steroid in the adrenal cortex

Pituitary growth hormone does not produce epiphysial closure, hence, gigantism can result from excessive pituitary growth hormone secretion Although the androgens stimulate growth, they also provide self-limitation of growth by closure of the epiphyses It is probable that they also inhibit pituitary growth hormone and thus cause the decrease in serum inorganic phosphorus and in plasma growth hormone concentration that occurs at puberty

In order to explore the mechanisms by which these hormones that influence growth exert their physiological effects, numerous experiments have been performed to study their effects upon protein and amino acid metabolism It is impossible to review completely the whole literature on this subject, but selected studies can be summarized

Growth hormone exerts a profound effect upon the nitrogen and fat metabolism of the mammal Lee and Ayres [3] observed that hypophysectomized rats lost more protein and less fat from their body stores than did pair-fed normal control animals over a period of 30 days Hoberman [4] investigated the metabolism of N^{15}-glycine in normal, hypophysectomized, and hypophysectomized–growth hormone–treated rats By analysis of the data on isotope distribution in tissue protein, plasma amino acid nitrogen and urinary nitrogen, he was able to calculate the rates of protein anabolism and catabolism, the rates of amino acid anabolism and catabolism, and the size of the amino acid pool He concluded that hypophysectomy caused a decrease in the rate of protein synthesis, an increase in amino acid catabolism, a decrease in the size of the amino acid pool, and no change in the other rates These alterations in the metabolism of nitrogen in the hypophysectomized rat were returned toward normal by the administration of growth hormone

Bartlett and Gaebler [5] studied the metabolism of N^{15}-glycine in the normal dog during nitrogen balance and after the injection of growth hormone that induced a positive nitrogen balance Analysis of the isotope data suggested that in this species as well as in the rat, growth hormone caused a reduction in the amino acid catabolism of tissue and an increased rate of protein synthesis Whether the effect upon protein synthesis or amino acid catabolism was primary could not be ascertained from the isotope data

In an attempt to delineate further the role of growth hormone, Russell [6] studied its effect on the rate of urea formation in nephrectomized animals, with and without administration of exogenous amino acids In these experiments, a single injection of growth hormone was given one hour prior to the beginning of observations on the blood urea nitrogen As is shown in figure 1, when no amino acids were given, the effect of growth hormone was negligible, if casein hydrolysate was administered, however, growth hormone had a marked effect, in proportion to dose, upon the rate of urea formation The nitrogen retained was converted to protein, since free amino acid levels in the blood actually fell during treatment with growth hormone In eviscerated, nephrectomized rats, Russell was able to show that growth hormone suppressed the rise in plasma amino acid nitrogen seen in control animals This observation in animals deprived of the liver, which is the chief site of amino acid catabolism, suggests that growth hormone is concerned chiefly with the reaction amino acids $\rightleftharpoons$ protein All of the data cited, including those obtained in isotope studies, support the view that the primary action of growth hormone is to promote the synthesis of tissue protein from cellular amino acids and thus shift the equilibrium toward protein anabolism

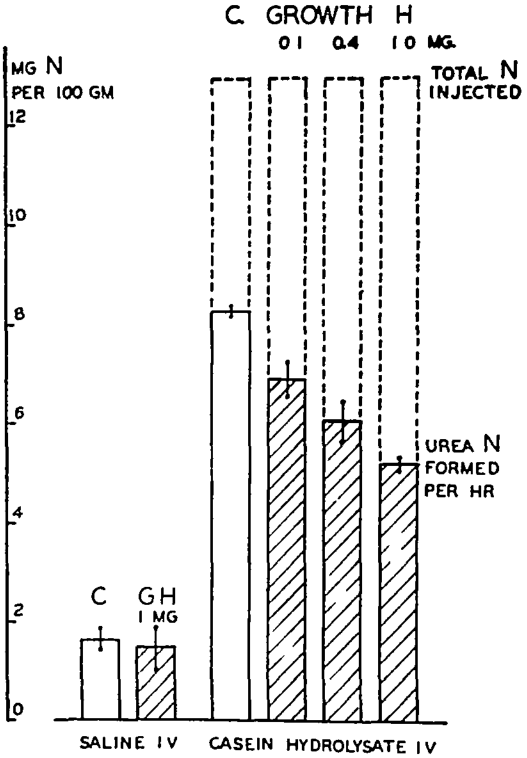


Fig 1 —Effect of growth hormone on rate of urea formation during first hour after infusion of saline solution and of casein hydrolysate in nephrectomized rats After Russell [6]

The action of growth hormone appears to be dependent upon normal energy production and utilization in tissues and upon the availability of substrate in adequate quantities Hazelwood, Bennett, and Nelson [7] have shown that the nitrogen-retaining effect of growth hormone is not seen in rats deficient in vitamin A, pyridoxine, pantothenate, choline, or protein When dietary protein is increased 6 to 24%, nitrogen retention on a fixed dose of growth hormone increases in the same proportion Beare, Beaton, and McHenry [8] observed similar negative effects of growth hormone therapy in rats deficient in riboflavin and pantothenate but noted that rats deficient in thiamine responded normally

Recently it was demonstrated that insulin is required for the optimum action of growth hormone Milman, DeMoor, and Lukens [9] found that three to four times the minimum maintenance dose of insulin was required in depancreatized cats to assure full responsiveness to growth hormone activity This observation holds an important clinical lesson for us If childhood diabetes is not treated vigorously, it may lead to significant dwarfism

The fact that both hypothyroid and hyperthyroid animals grow poorly and are distinctly less responsive to growth hormone than are normal animals focuses interest on the influence of thyroid hormone upon protein metabolism There is definitely an optimum thyroid hormone level for normal protein metabolism.

Protein Metabolism in Various Thyroid Conditions in Man

Condition	No of Patients	Rate of Protein Synthesis Mg of Nitrogen/Kg /Day
Hypothyroid	6	3.4
Euthyroid	4	7.6
Hyperthyroid	1	12.6

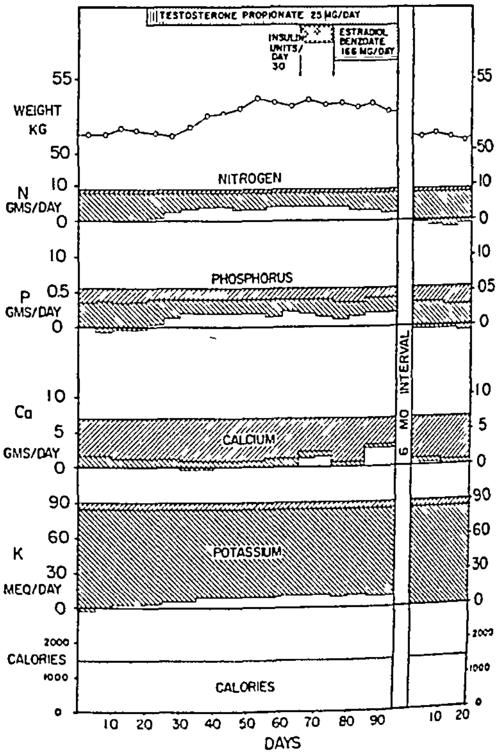

Fig 2 —Metabolic study of effect of testosterone propionate in woman, aged 25 with osteoporosis due to adrenal cortical hyperfunction (Cushing's syndrome) Redrawn from Albright and others [11]

Crispell, Parsons, and Hollifield [10] have shown by means of isotope techniques that the rate of protein synthesis is decreased in both myxedema and hyperthyroidism Their data are presented in the table The response of myxedematous patients to L triiodothyronine was slow Initially, there was a marked negative nitrogen balance as edema fluid containing protein was mobilized, and there was no increase in the rate of protein synthesis for an appreciable period of time in the treatment The mode of action of thyroid hor mone is still unknown The postulate that it produces adverse metabolic effects in hyperthyroid states by uncoupling oxidative phosphorylation is now being questioned It seems very clear that growth hormone is dependent for its efficacy upon several variables These include a normal nutritional status with an adequate intake of calories, protein, and vitamins, and a normal underlying endocrine structure, with particular reference to insulin and thyroxin

Androgens play a major role in stimulating growth and a positive nitrogen balance, especially in adolescence Available evidence suggests that androgens, like growth hormone, influence the reaction amino acids $\rightleftarrows$ protein, in the direction of protein synthesis Whether they do so by promoting anabolism of tissue protein from amino acids or by inhibiting catabolism of tissue protein to amino acids is not settled It has been observed in man that panhypopituitarism, which is unresponsive to growth hormone therapy, responds to testosterone propionate therapy with a typical protein anabolic effect Testosterone, in contrast to growth hormone, may influence nitrogen balance favorably in patients who exemplify unfavorable conditions for anabolism, such as those with adrenal cortical hyperfunction (Cushing's disease) and those who are undergoing weight reduction on low-calorie, low-protein diets The response of a patient with adrenal cortical hyperfunction to testosterone therapy is shown in figure 2 [11]

The response to androgen is not dependent upon the pituitary, the adrenal cortex, or the pancreas in the alloxan-diabetic rat Sirek and Best,[12] however, have shown that depancreatized dogs do not respond to testosterone given intramuscularly with the usual fall in plasma amino acid nitrogen and a positive nitrogen balance unless insulin is added to the regimen Homburger and Pettengill [13] have shown that both diet and genetic strain affect the response of mice to androgen Although the renotropic, clitorotropic, and adrenal suppressor effects of testosterone given intramuscularly were regularly noted, markedly restricted diets (in calories or protein), exceptionally high-protein diets, or variant strains of mice abolished the anabolic response to testosterone Although androgens appear to be more independent of nutritional status and of the intactness of other endocrine glands in exercising their anabolic effects than does growth hormone, the physiological activity of the androgens does not exist *in vacuo* but is related to many conditions of cellular physiology

Starvation

Caloric undernutrition, partial or absolute, is a stress for the mammal, and appropriate adaptation to it requires the interplay of endocrine factors It has been amply demonstrated that persons subjected to ablation or inactivation of the adrenal cortex or pituitary tolerate starvation poorly, fail to conserve their tissues in an appropriate way, and rarely survive a prolonged fast The following marked changes in endocrine activity occur with prolonged undernutrition amenorrhea in females and aspermatogenesis in males, decreased metabolic rates, pigmentations of the skin, hypotension, and weakness attributed to attenuated function of the pituitary, thyroid, adrenals, and gonads in association with malnutrition In Zubiran's [14] study, involution and atrophic changes in the glands were demonstrated in material from 195 autopsies Diminished functional activity was demonstrated by hormonal determinations in 201 patients and other functional tests in an additional 318 patients Lowered pituitary activity with diminished trophic hormone secretion was thought to precede the changes in the target organs, and, with improvement in nutritional status, normal function was reestablished in most cases

In acute starvation, the changes in endocrine activity are phasic, with secretion of large amounts of hormone by some glands during the transition from the fed to the fasting state and decreased output once a fasting state has been established In figure 3 are presented the balances of nitrogen, potassium, and sodium for the famous Levanzin during the period of his 31-day fast that was studied by Benedict in 1915 [15] It may be noted that total urinary nitrogen excretion increased from 7 Gm on the 1st day to 11 Gm on the 4th and then gradually diminished to 7 Gm again on the 31st day The first increase undoubtedly represents the loss of liver glycogen and other labile carbohydrate during the first two days of the fast with consequent loss of its protein-sparing ability This increased catabolism of protein is largely dependent upon 11-oxycorticoids acting to increase gluconeogenesis The second phase of change in nitrogen excretion, which is a slow decline from the 4th to the 31st day, is associated with a gradual decrease in over-all metabolic rate, a decrease in body size, and a diminution of the output of hormones by the pituitary, thyroid, and adrenal cortex Urinary potassium excretion paralleled the urinary nitrogen excretion during the fast, as might be expected from the mobilization of lean body tissue

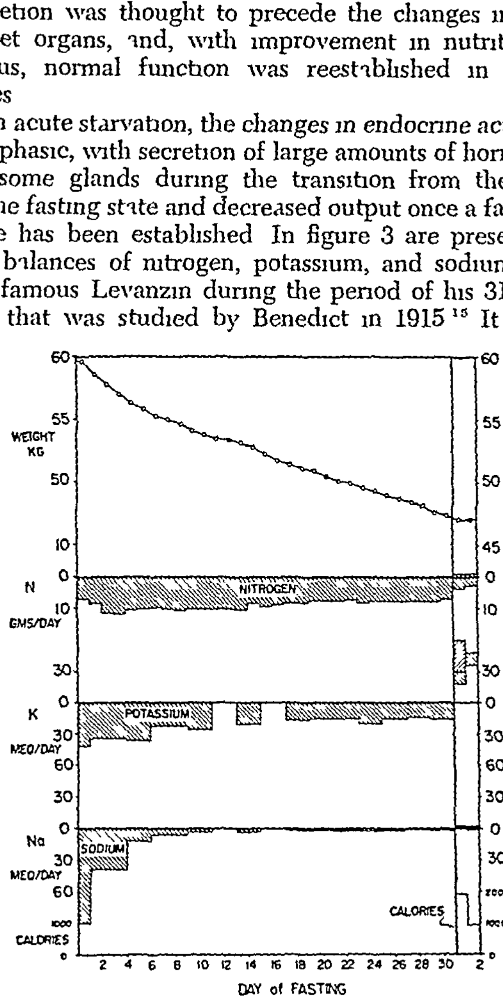

Fig 3 —Metabolic study of man aged 40, who voluntarily underwent 31-day fast Redrawn from Benedict [15]

except during the first few days when extra potassium was excreted during deglycogenation Urinary sodium excretion was markedly decreased after the second day of the fast, presumably as a result of increased aldosterone secretion, an effect that persisted during the fast despite a presumed decline in pituitary hormone level

Another case is that of a 36-year-old schizoid white male who voluntarily undertook a 30-day fast in order to improve his mind He lost 16 kg (35 lb) in weight over the month of his fast prior to admission to our metabolic unit and at that time showed all the signs associated with starvation He was 69 in (175 cm) tall, weighed 46 3 kg (102 lb), had a blood pressure of 70/40 mm Hg, and a pulse rate of 60 He was cold, weak, and acrocyanotic Urinalysis revealed a specific gravity of 1 009, acetone 4+, and sugar, albumin, and sediment negative The hematocrit reading was 50%, and the white blood cell count was 8,200 per cubic millimeter The blood sugar level was 56 mg per 100 cc, serum nonprotein nitrogen, 39 mg per 100 cc, total serum protein, 7 3 Gm per 100 cc, with an albumin-globulin ratio of 1 7, serum sodium level, 138 mEq per liter, serum potassium level, 5 3 mEq per liter, serum chloride level, 111 mEq per liter, and carbon dioxide, 25 mEq per liter Oxygen consumption was 155 cc per minute, equivalent to a basal metabolic rate of -30% The patient was placed on a metabolic-balance study and maintained in the fasting state for three days, whereupon he was repleted nutritionally by gradually increasing amounts of food over a 17-day period The balance data of his inpatient stay are presented in figure 4 The details of this study are presented elsewhere [16]

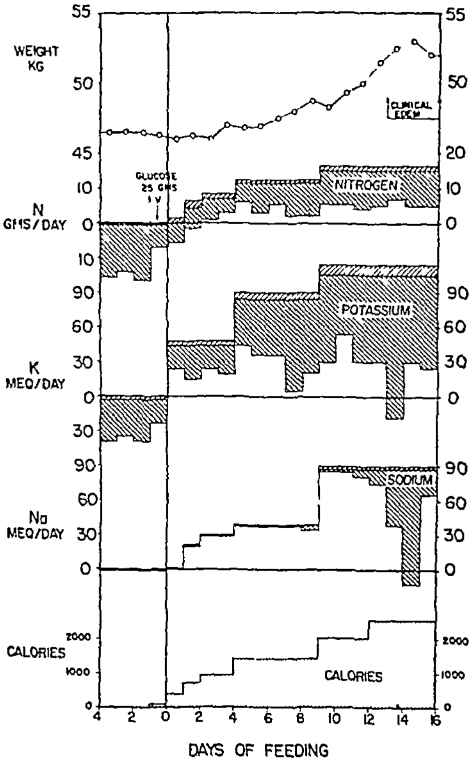

Fig 4 —Metabolic study of nutritional repletion of man, aged 37, who had undergone 33-day fast

On the patient's admission, the fasting plasma 17 hydroxycorticoids were 28 mcg per 100 cc, his urinary nitrogen level 15 Gm, and his urinary potassium output 40 mEq per day The reduction in urinary nitrogen and potassium seen in Levanzin on his 30th day of fasting was not noted in this patient, possibly because of less reduction in adrenal cortical activity in our patient during the fast When the patient's fast was broken by the administration of 25 Gm of dextrose intravenously on his 34th day, the carbohydrate produced both a nitrogen-sparing and a potassium sparing effect Thereafter he was fed by mouth, and promptly the nitrogen, potassium, and sodium balances became positive His retention of sodium was conspicuous, in fact, he excreted practically no sodium despite increased sodium intake for almost two weeks and developed clinical edema on the 15th day This behavior is typical of that of many starved patients upon refeeding and is a variant of starvation edema The serum protein levels were normal throughout the study Whether excessive aldosterone secretion persists into the period of refeeding a starved person or whether other changes in renal physiology persist to provide the basis of the abnormal sodium retention is a subject of continuing study

Fasting provides a stress that invokes an adrenal cortical discharge which stimulates gluconeogenesis from protein and possibly from fat Adequate sodium retention is assured through activation of mechanisms (not mediated via the pituitary) of aldosterone secretion During continued fasting, anterior pituitary secretions are reduced, with concomitant reduced activity of the thyroid, gonads, and adrenal cortex With prolonged chronic undernutrition, atrophy of these glands may occur

Diabetic Acidosis

Diabetes mellitus results from a disparity in the rate of insulin secretion by the pancreas and its demand by other tissues In many instances, particularly in overweight, middle-aged diabetics without ketosis, appreciable amounts of insulin are secreted [17] In these patients with more mild, nonketogenic diabetes, diet therapy is usually effective, insulin is rarely needed, and negative nitrogen balance is not seen On the other hand, patients with the juvenile type of diabetes tend to secrete little, if any, insulin They require insulin for maintenance, and, upon withdrawal of insulin, they develop ketosis, acidosis, and marked negative nitrogen balances The onset of ketosis in such diabetics is followed by an increase in 17 hydroxy-11-oxycorticoids in both plasma and urine, with an increase in gluconeogenesis

A study of the disposition of C^{14}-glucose in persons with stable, nonketogenic diabetes and in those with labile, ketogenic diabetes by Miller and his colleagues [18] has shown that, whereas the former group exhibited normal rates of turnover and oxidation of glucose to carbon dioxide, the latter group demon strated both overproduction and decreased oxidation of glucose to carbon dioxide Increased hepatic gluconeogenesis in persons with labile diabetes has been shown by Beam, Billing, and Sherlock [19] to be quickly reduced by insulin therapy

In figure 5 are charted the metabolic balances for nitrogen, potassium, and sodium in a young person with ketogenic diabetes studied by Atchley and coworkers [20] While receiving 85 units of insulin per day, this diabetic was in nitrogen, potassium, and sodium balance and excreted no sugar or ketone bodies in his urine Upon cessation of insulin therapy, however, the development of acidosis was rapid It was indicated by the prompt appearance of acetone and sugar in the urine, decrease in blood bicarbonate, loss of sodium and water, and onset of nausea, vomiting, and prostration These changes were accompanied by catabolism of lean body tissue, with concomitant losses of nitrogen and potassium As is shown in figure 5, administration of insulin quickly reversed these changes The effect of insulin in ketogenic diabetes illustrates well its anabolic effect The interrelationship of insulin with growth hormone and androgens in promoting anabolism of protein has been mentioned earlier in this discussion

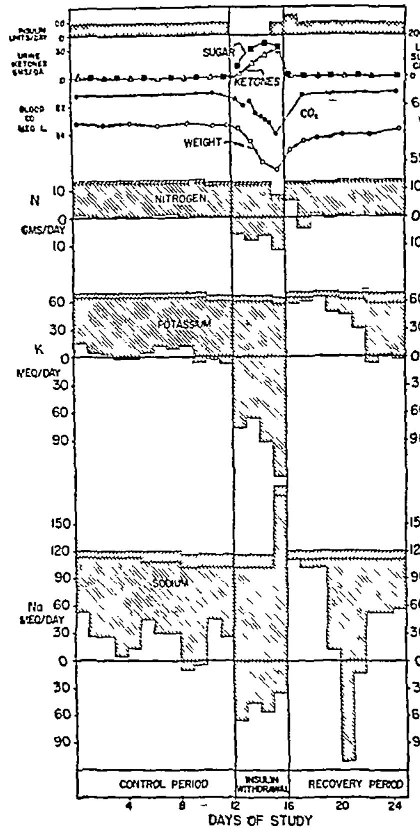

Fig 5—Metabolic study of man aged 25 with ketogenic diabetes from whom insulin was withdrawn and then reinstated Redrawn from Atchley and others [20]

Although the mode of action of insulin has been the subject of intensive research for over 30 years, its precise biochemical function is not known Recent studies by Levine and Goldstein [21] suggest that insulin is concerned with the control of the permeability of cells to glucose Whether this single mode of action can account for the multiple effect of insulin activity, that is, increased glucose oxidation, improved oxidative phosphorylation, increased lipogenesis, decreased gluconeogenesis, and increased protein anabolism, is controversial at the present time The proponents of this hypothesis argue that the greater availability of glucose within the cell would initiate reactions leading to these multiple effects Further research is necessary to establish, with certainty, the exact locus or loci of insulin action

Trauma

Selye [22] advanced the idea that many kinds of nonspecific somatic trauma could elicit a stereotyped physiological response dominated by adrenal cortical discharge There is little doubt that some variant of this general adaptation syndrome is seen in many conditions in man The evidence for such a response in starvation and in diabetic acidosis has been stated Other stresses that provide such responses include infections, burns, intoxications, cold, muscular fatigue, and trauma—both surgical and nonsurgical

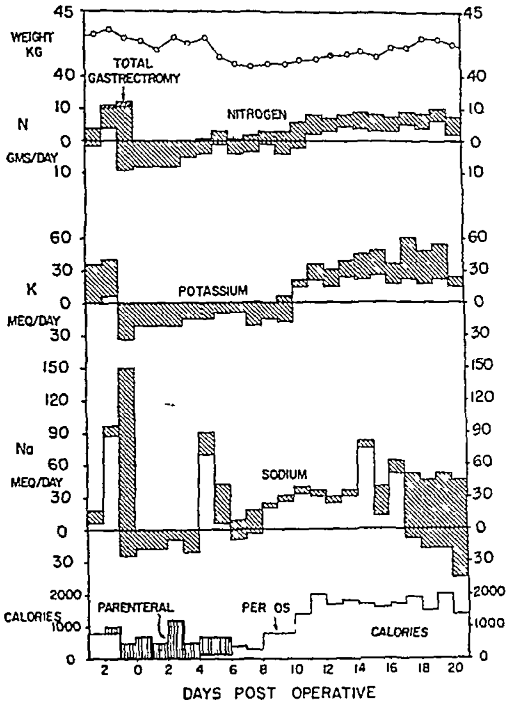

Fig 6—Metabolic study of female, aged 66, who underwent total gastrectomy Redrawn from Moore [23]

The metabolic response to surgery has been the subject of extensive studies by Moore and Ball [23] A metabolic balance study of one patient is presented in figure 6 This response followed a transthoracic total gastrectomy, splenectomy, and pancreatectomy Although nitrogen and caloric intakes were not optimum immediately after surgery, nitrogen catabolism was excessive and was not spared by glucose infusions Potassium losses and sodium retention also characterized the immediate postoperative period, and not until approximately 15 days after the operation did positive nitrogen and potassium balances ensue, followed by sodium diuresis. Whether the negative nitrogen and potassium balances would have been so large had the patient been more adequately fed during the immediate postoperative period is answered by the data of Wilkinson and associates.[24] They found that amino acids given intravenously and/or feeding in the immediate postoperative period did not improve nitrogen balance after surgery. In figure 7 is presented a study by Howard and co-workers[25] of a 24-year-old healthy white male with a fractured tibia, who, despite adequate nitrogen and caloric intakes during the post-traumatic period, showed the same extensive period of negative nitrogen balance. This phase of the response to injury is associated with an increased secretion of adrenal cortical hormones that are at least partially responsible for it.

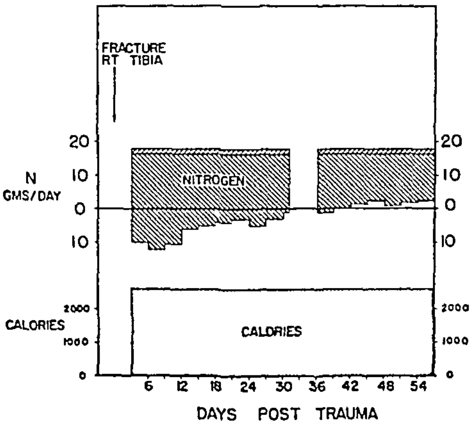

Fig 7.—Metabolic study of young man during convalescence from major skeletal fracture. Redrawn from Howard and others.[25]

Moore[23] reports that a sizable catabolism of nitrogen after injury is correlated with a prompt recovery. Nutritionally depleted patients lose less nitrogen after injury but, in general, also have a poorer anabolic phase and a less satisfactory convalescence. The diet therapy of surgical and other patients suffering trauma should be designed with endocrine responses in mind. Whenever possible, it is important to replete undernourished individuals, prior to surgery, with diets rich in protein and other essential nutrients. It is not wise, however, to force-feed during the immediate postoperative period when nutrients are not well assimilated and the organism is in a catabolic phase. It is equally important to supply calories and other nutrients in increased amounts during the period of anabolism. The increased appetite of the patient is often a guide to the time of onset of this period.

Inflammation

Since the demonstration by Hench and associates,[26] in 1950, of the anti-inflammatory properties of cortisone given in pharmacological amounts to patients with rheumatoid arthritis, tremendous strides have been made in the treatment of other nonbacterial inflammatory diseases. Rheumatic fever, lupus erythematosus, scleroderma, asthma, urticaria, exfoliative dermatitis, ulcerative colitis, lymphoma, and nephrosis are some diseases in which corticoid therapy may cause dramatic improvement.[27]

One may ask how it is possible to stimulate recovery from disease and promote health with agents that are associated with catabolic effects on metabolism. In most instances the early negative nitrogen balance, which occurs after initiation of corticoid therapy, diminishes, and a positive nitrogen balance is obtained with weight gain and actual increase in lean body mass. The antiphlogistic effect of the steroids, which counters the catabolic effect of the inflammatory process may greatly outweigh the catabolic effect of the steroids themselves. The paradox of treating a catabolic state with a catabolic agent has been considered by Roberts,[28] who has adduced evidence to show that one of the primary roles of adrenal cortical hormones is the mobilization of tissue protein. The final translocation of this protein is determined by the needs of the organism. The hepatectomized rat, for example, uses protein and amino acids derived from other labile stores for the regeneration of the liver, and the same may be true for the patient with hepatitis. In the well-nourished patient without such a need, the labilized protein may be catabolized and appear in the urine as urea. In many instances, the nitrogen balance may be shifted by increasing the intake of dietary protein. It has also been pointed out that increasing the dietary potassium may not only improve the potassium balance but may actually decrease the catabolic response of the organism to adrenal cortical hormones.

Comment

The effect of the various hormones discussed upon protein metabolism is dependent upon a number of variables that include diet, previous nutritional status, intactness of other endocrine organs, and the genetic differentiation of enzymatic patterns. Only with a knowledge of all these parameters is it possible to predict with any certainty the effect of a given hormone on protein or intermediary metabolism. Figure 8 is a diagrammatic summary of our knowledge of the action of the hormones in reference to certain pathways of intermediary metabolism. The studies to date strongly suggest that those hormones which affect protein metabolism act mainly to influence the equilibrium amino acids $\rightleftarrows$ protein

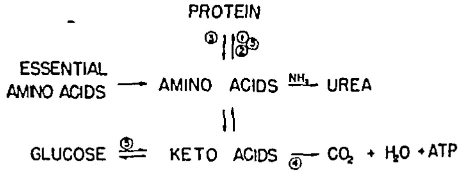

Fig 8.—Action of hormones in reference to certain pathways of intermediary metabolism. Hormones are indicated as influencing reactions shown in direction of arrow nearest number. Hormones listed are (1) growth hormone, (2) androgen, (3) adrenal corticoids, (4) thyroid hormone and (5) insulin.

Pituitary growth hormone, insulin, and androgens are protein-anabolic in over-all effect, although it appears from the data available that their specific modes of action are different Androgens appear to be anti catabolic, growth hormone proanabolic, and insulin proanabolic, although it is possible that insulin acts indirectly through its effect upon glucose uptake The specific action of thyroxin is unknown It appears to be protein-anabolic under certain conditions and protein-catabolic under others, it is certainly prometabolic The corticoids appear to be protein-catabolic but probably not amino acid-catabolic, since the net effect of corticoid action upon gluconeogenesis and urea formation is quite variable Information about these interrelationships is incomplete, but progress is being made in defining the role of the hormones in relation to cellular physiology An area for continuing intensive research is the precise function for a hormone at the molecular level

The homeostatic responses that occur in growth, starvation, and injury are governed in an important way by intricate changes in hormonal secretion The metabolic changes that occur in diabetes mellitus and after the administration of cortisone for the control of inflammatory disease involve other endocrine adjustments that must also be appreciated if optimum management is to be instituted Diet therapy bears an important relationship to optimum management in all of these states, the need for and acceptability of nutrients —not only dietary protein, but others—must be understood if optimum growth, convalescence, and health are to be obtained Endocrinology and nutrition are inseparably associated at the cellular level, their important interrelationship should be understood in the practice of medicine as well

FOREIGN SCHOLARS IN THE MEDICAL SCIENCES

During the latter part of June a three-day conference on medical education for foreign scholars in the medical sciences was held at the University of Wisconsin The conference was financed by the China Medical Board of New York, Incorporated and cosponsored by that board the Association of American Medical Colleges, and the Conference Board of Associated Research Councils It was attended by about 50 selected foreign scholars and about 20 American educators

The three day discussions were centered around the philosophy of higher education in the United States, the education of a physician in the United States, evaluation of the applicant for medical education, the organization and objectives of a medical school, the development of the medical curriculum, and recent trends in medical education After the presentation of papers on the aforementioned topics the conferees were divided into small discussion groups in which exceedingly stimulating and valuable exchange of opinion occurred

Although the conference was designed primarily to give the foreign scholars a comprehensive insight into the philosophy and methodology of medical education in the United States, it served as an effective “two-way street in giving the guest faculty an insight into the educational philosophy and methodology of the nations represented by the guest scholars One attending this conference gained the impression that there is deep concern and interest in the problems of medical education wherever it is being conducted This is manifested by the experimental approaches that are being utilized by schools in other countries and that are designed to meet their needs in the education and training of medical personnal

Although the basic objectives of medical education in different areas of the world appear to have a universal character, special needs necessitate wide variations in emphasis and approach in curriculum content as well as in educational philosophy and methodology The pattern most satisfactory and best adaptable to our needs might fall short of meeting those of other areas One cannot participate in a conference of this type without gaining increasing respect and admiration for the fine contributions to medical education and knowledge that are being made throughout the world It emphasized the constant challenge and value of intercommunication between all nations in the important and dynamic field of medicine An experience with a group such as this also emphasizes the importance of making our best education and training experiences available to competent foreign scholars so that they may return to their homes with an appreciation of a thoroughly worthwhile experience while in the United States It is to be hoped that conference of this nature can be developed in various areas throughout the United States where groups of foreign scholars in medical sciences are sufficiently large to merit such efforts

POSTGRADUATE MEDICAL EDUCATION

The third annual list of postgraduate courses for physicians appears in this issue of THE JOURNAL (page 1773) as compiled by the Council on Medical Education and Hospitals of the American Medical Association It deserves the attention of all physicians in the United States The list should serve as a ready reference throughout the year beginning September 1, 1957 Since 1938, lists of courses for the continuation education of physicians have been published in THE JOURNAL, at first quarterly, then semiannually, and annually beginning in 1955

The present list, as was also the case last year, includes only the various kinds of primarily educational postgraduate programs that appear to be courses Although physicians also continue their education by reading of the medical literature, by consultations with colleagues, by attendance at hospital conferences, and by attendance at medical society conventions, assemblies, and meetings, the Council on Medical Education and Hospitals believes that it is most useful to the profession and to the further increase in quality of the courses themselves if the annual listing concentrates on the more formal course type of postgraduate medical education Lists of medical society conventions, assemblies, and meetings have for some time been published monthly elsewhere in THE JOURNAL

It is important to note that, unlike such other lists as those of medical schools, internships, and residencies published annually by the Council on Medical Education and Hospitals, the lists of postgraduate courses are not based upon survey or inspection and thus do not represent approval by their inclusion in the list nor disapproval by omission from the list The list is published on the basis of replies to inquiries made to *the medical schools, hospitals, and* medical societies in the United States Every effort is made to make the list as complete as possible in order to provide a single reference for physicians who wish to continue their education It is probable that the educational value of the courses varies considerably

The Council on Medical Education and Hospitals has become increasingly concerned with the whole field of postgraduate medical education because it involves, or should involve, all of the medical profession throughout the 40 or more years of practice of its members The field has been extensively and carefully studied by the Council More than a year ago, to secure broad-based recommendations for a program of action the Council could take to be of assistance in the further development of postgraduate medical education, an *ad hoc* Advisory Committee for Postgraduate Medical Education was appointed, it is still active It consists of some of the leaders in medical education from the viewpoint of medical schools, of hospitals, and of medical societies, with the viewpoints of private general practice and of specialty practice also represented The advisory committee was requested to study the field and its problems and to recommend a program through which the Council can be of assistance The beneficial influence of the Council on Medical Education and Hospitals in undergraduate and graduate medical education is generally recognized It was thought that the Council might have an equally effective influence, in cooperation with the other interested organizations, in the important postgraduate phase of medical education

Such a long-range program is being developed Although continuation education has some unique features as compared with undergraduate and graduate medical education, the advisory committee and the Council believe that the experience gained from the growth of undergraduate and graduate medical education to its present high level of effectiveness can be applied to education in the postgraduate period Certain common denominators of medical education discovered during the growth of undergraduate and graduate medical education can be applied fully to postgraduate medical education to serve as a guide to those sponsoring the more formal courses and other programs A concomitant initial approach was the development of a statement of objectives for this field of medical education, on the assumption that a common purpose generally agreed upon can provide a useful focus for activities in this field Therefore, the first task which the advisory committee undertook was the development of a guide that included a statement of objectives as well as of basic principles regarding postgraduate medical education programs This guide was endorsed by the Council and, in June, 1957, was adopted by the House of Delegates of the American Medical Association for publication and general distribution It has been mailed to those known to be interested and active sponsors in this field The guide is available upon request to the Council on Medical Education and Hospitals of the American Medical Association

Another part of the over-all program that the advisory committee recommended is that the Council increase its activities as a national center of information on postgraduate programs Toward the accomplishment of this, it seemed desirable that all information on postgraduate courses and related activities channel through the Council offices The Editor of THE JOURNAL and the Council staff agreed early this year that it would be more appropriate and useful for all notices of postgraduate courses to come through the Council offices than for notices supplementary to the annual list to be published independently in the Medical News section of THE JOURNAL It is hoped that such publication of supplementary notices under the Council heading is an interim measure only, becoming unnecessary when all courses are planned far enough in advance for inclusion in the annual list It should be noted that one of the basic principles in the guide for postgraduate medical education programs is that "the curriculum of any postgraduate medical education program should be the result of thoughtful planning well in advance of the date scheduled for the beginning of the program The value of a postgraduate program depends to a considerable extent on the amount of thoughtful planning that occurred months in advance of its beginning "

Before the guide was submitted to the House of Delegates of this Association, various organizations were shown copies of preliminary drafts and their suggestions were solicited, in order that all those groups who are thoughtfully concerned with post graduate medical education can proceed in a concerted manner, as well as to tap their resources of experience These organizations include the Association of American Medical Colleges, the American Academy of General Practice, the American College of Physicians, the American College of Surgeons, and the Advisory Board for Medical Specialties It was not intended that these organizations approve the guide before it was approved by the parent organization, the House of Delegates of the American Medical Association It was considered important that the major interested groups have an informal opportunity to participate in its formulation As with all other guides and essentials published by the American Medical Association, it is expected that this guide will undergo evolution and revision

ORGANIZATION SECTION

REPORT OF THE SECTIONS OF THE SCIENTIFIC ASSEMBLY

NEW YORK MEETING, JUNE 3-7, 1957

SECTION ON ANESTHESIOLOGY

The Section on Anesthesiology met on Wednesday and Thursday morning June 5 and 6, in the Terrace Room of the Plaza Hotel, and on Wednesday afternoon, June 5, met jointly with the Section on Diseases of the Chest in the Tudor Room of the Henry Hudson Hotel

Dr Scott M Smith, Chairman, Salt Lake City, presided over the meeting on Wednesday morning, and Dr Richard H Barrett, Vice-Chairman, Hanover, N H, presided on Thursday morning Dr John F Briggs, St Paul, Chairman of the Section on Diseases of the Chest, presided over the joint meeting on Wednesday afternoon The Scientific Program was presented as listed in the Official Program with the exception of one discussor, Dr Paul H Lorhan, Kansas City, Kan, who was ill and unable to attend

At a business meeting held on Wednesday, June 5, the Section voted to establish the office of Secretary-Elect for a term of three years, at the end of which time the Secretary-Elect will automatically assume the duties of Secretary (If the office of the Secretary is vacated prior to the normal three-year period, the Secretary-Elect will become Secretary)

At the Wednesday morning session, the Section Delegate, Dr Edward B Tuohy, Los Angeles, reported on the activities of the House of Delegates of the American Medical Association, and the Section Representative to the Scientific Exhibit, Dr Edwin L Rushia, Augusta, Ga introduced the Scientific Exhibitors

The following officers were elected Chairman, Dr Kenneth McCarthy, Toledo, Ohio, Vice-Chairman, Dr Joseph H ailing, Los Angeles, Secretary, Dr Daniel C Moore, Seattle, Secretary-Elect, Dr Vincent J Collins New York, for a term of one year since the Secretary s term expires in 1958, Delegate, Dr Edward B Tuohy, Los Angeles Representative to the Scientific Exhibit, Dr Edwin L Rushia, Augusta, Ga, and Representative to the American Board of Anesthesiology, Stuart C Cullen, Iowa City

At the end of the last session on Thursday morning, the Alternate Delegate, Dr Urban H Ebersole, Boston, reported on the actions of the House of Delegates, since the Delegate, Dr Edward B Tuohy was detained in the session of the House of Delegates

SECTION ON DERMATOLOGY

The Section on Dermatology met on Wednesday, Thursday and Friday mornings in the Tudor Room of the Henry Hudson Hotel The Chairman Dr Herbert Rattner Chicago presided

At the first session on Wednesday, the Section Delegate Dr Winfred Showman Tulsa, Okla, presented his report, outlining the actions taken at the current session of the House of Delegates, Dr Stanley Huff, Chicago presented the report of the Committee on Scientific Exhibits, Dr Beatrice Kesten, New York, reported to the Section on the activities of the American Board of Dermatology, Dr Herbert Rattner, Chicago, reported to the Section on the activities of the Editorial Board of the A M A *Archives of Dermatology,* and Dr John Downing of Boston read the report of the Committee on Industrial Dermatoses The Section established the position of Assistant Secretary for a term of one year

All papers were presented and discussed by the authors and discussors as listed in the official program

At the session on Thursday morning, the following officers were elected Chairman, Dr Earl D Osborne, Buffalo, Vice Chairman, Dr Leslie M Smith El Paso, Texas, Assistant Secretary, Dr Edward P Cawley, Charlottesville, Va The terms of office of the Secretary, Dr Clarence S Livingood, Detroit, Delegate, Dr Winfred Showman, Tulsa, Okla, and Alternate Delegate, Dr Maurice Costello, New York, do not expire until 1958 Dr J Walter Wilson, Los Angeles was appointed Representative to the American Board of Dermatology for a term of three years

At the close of the last session, the new Chairman of the Section, Dr Earl Osborne, and the Vice-Chairman, Dr Leslie Smith, were presented

SECTION ON DISEASES OF THE CHEST

Two meetings of the Section on Diseases of the Chest were held in the Tudor Room of the Henry Hudson Hotel on Tuesday and Wednesday afternoon, the second meeting being held jointly with the Section on Anesthesiology The third meeting of the Section was a joint meeting with the Section on Radiology and was held in the Ballroom of the Henry Hudson Hotel, Thursday afternoon

At the business meeting on Wednesday, June 5, the following officers were elected Chairman, Dr John F Briggs, St Paul, and Vice-Chairman, Dr M Jay Flipse, for the ensuing year, Secretary, Dr Burgess L Gordon, Philadelphia, for the ensuing four years, Delegate, Dr Hollis E Johnson, Nashville, Tenn, for the ensuing year, and Representative to the Scientific Exhibit, Dr Edwin R Levine, Chicago, for the ensuing year

SECTION ON EXPERIMENTAL MEDICINE AND THERAPEUTICS

The sessions of the Section were held in the Ballroom of the Plaza Hotel on Tuesday, Wednesday, and Thursday afternoon, June 4, 5, and 6, the Thursday afternoon session being a joint meeting with the the Section on Internal Medicine

At the business meeting on Wednesday, June 5, the following officers were elected Chairman, Dr George E Burch, New Orleans, Vice-Chairman, Dr Charles H Burnett, Chapel Hill, N C, Secretary, Dr Elliot V Newman, Nashville, Tenn, Delegate, Dr Edgar V Allen, Rochester, Minn, Representative to the Scientific Exhibit, Dr Joseph F Ross, Los Angeles

SECTION ON GASTROENTEROLOGY AND PROCTOLOGY

Meetings of the Section on Gastroenterology and Proctology were held on Wednesday, Thursday, and Friday mornings, June 5, 6, and 7, in Room 4 on the 4th floor of the Coliseum The Friday morning meeting was held jointly with the Section on Pathology and Physiology

At the business meeting on Thursday, June 6, the following officers were elected for the ensuing year Chairman, Dr Everett D Kiefer, Boston, Vice-Chairman, Dr A W Martin Marino Brooklyn, N Y, Secretary, Dr William H Dearing, Rochester, Minn, and Representatives to the Scientific Exhibit, Dr Gordon McHardy, New Orleans, and Dr Willard H Bernhoft, Buffalo The present Delegate, Dr Stuart T Ross Garden City N Y, and Alternate Delegate, Dr Garnet W Ault, Washington, D C, remain in office for one more year

SECTION ON GENERAL PRACTICE

The Section on General Practice met in the Ballroom of the Henry Hudson Hotel on Tuesday and Wednesday afternoons June 4 and 5 It held a joint meeting on Friday morning, June 7 with the Section on Urology in the Colonnades Room of the Essex House All papers and discussions were presented as listed in the official program

At the business meeting on Wednesday afternoon, June 5, the following officers were elected Chairman, Dr Charles E McArthur Olympia, Wash and Vice-Chairman, Dr S A Garlan, New York, for the ensuing year The terms of the following officers end in 1958 Secretary, Dr Eugene I Baumgartner, Oakland Md Delegate, Dr Lester D Bibler, Indianapolis, Alternate Delegate Dr Milton B Casebolt, Kansas City, Mo, and Representative to the Scientific Exhibit, Dr I Phillips Frohman, Washington, D C

SECTION ON INTERNAL MEDICINE

A luncheon meeting of the Past-Chairmen, the present Executive Committee, and the Trustees of the Billings Fund of the Section on Internal Medicine was held at the Plaza Hotel, New York, on Wednesday, June 5 Those present were Dr A Carlton Ernstene, Chairman, and Drs Walter L Bierring, Howard P Lewis, Walter L Palmer, Charles T Stone, William D Stroud Henry M Thomas Jr, and R H Kampmeier The minutes of the Executive Committee on June 12, 1956, were read and approved It was announced that Dr Richard B Capps, nominated as Alternate Delegate to the House of Delegates at the 1956 meeting was unable to accept the nomination Dr Truman G Schnabel was nominated by letter ballot to this position subsequent to the last meeting Furthermore, it was announced that Dr Robert Loeb of New York declined the Billings Lectureship Dr John R Paul of New Haven, Conn, was out of the country, and therefore Dr C Sidney Burwell of Boston was selected to give the lecture

The scientific program of the Section for 1958 was discussed It was voted to hold again a Joint Session with the Section on Experimental Medicine and Therapeutics After discussion of what might be done to improve attendance at the Section Meetings, the Secretary was instructed to explore the possibility of mailing preliminary programs to those registering for the Section on Internal Medicine in the recent previous years

The following officers were elected Chairman, Dr Albert M Snell, Palo Alto, Calif, Vice Chairman, Dr Thomas P Findley Jr, Augusta, Ga, Secretary, Dr Rudolph H Kampmeier, Nashville, Tenn and Representative to the Scientific Exhibit, Dr Henry T Ricketts, Chicago Dr Charles T Stone Sr of Galveston, Texas, and Dr Truman G Schnabel, Philadelphia, continue as Delegate and Alternate Delegate, respectively, to the House of Delegates until Jan 1, 1959 There are no vacancies on the Board of Trustees of the Billings Fund Dr Wendel M Stanley, Berkeley, Calif, was selected as the Billings Lecturer for 1958 Drs John R Paul, New Haven, Conn and George W Thorn, Boston, were chosen as first and second alternates respectively

The scientific meetings of the Section were held on Wednesday and Thursday mornings, June 5 and 6, and Thursday afternoon, June 6, in the Ballroom of the Plaza Hotel, the third session being a joint meeting with the Section on Experimental Medicine and Therapeutics All papers and discussions were presented as listed in the official program

SECTION ON LARYNGOLOGY, OTOLOGY, AND RHINOLOGY

The Section on Laryngology, Otology, and Rhinology held its sessions in the Ballroom of the Park Sheraton on Tuesday, Wednesday, and Thursday afternoon, June 4, 5, and 6 Dr Kenneth L Craft Indianapolis, Vice-Chairman of the Section, presided in the absence of the Chairman, Dr Gordon D Hoople of Syracuse N Y, who was ill and unable to attend the meeting It was voted to send Dr Hoople regrets of his illness and hopes for his speedy recovery The Secretary of the Section, Dr Hugh Kuhn, read the Chairman's address All other papers were read and discussed as presented in the Official Program

The Section voted that any funds now in the possession of the Section or which may come into the possession of the Section be managed by the current Chairman, Vice-Chairman and Secretary Dr Walter Heck Representative to the Scientific Exhibit was given a vote of thanks for organizing the excellent scientific exhibits for the Section The Chairman called attention to the honors given three exhibits in the Section

The following officers were elected Chairman, Dr Alden Miller Los Angeles Vice-Chairman Dr Lester Brown Atlanta, Ga, and Representative to the Scientific Exhibit, Dr Walter E Heck, San Francisco for the ensuing year The Secretary Dr Hugh A Kuhn, Hammond, Ind, was elected in 1956 for a term of three years, ending in 1959 The Delegate Dr Gordon F Harkness Davenport, Iowa, and the Alternate Delegate Dr Dean Lierle Iowa City, were elected in 1955 for two-year terms ending Dec 31, 1957

SECTION ON MILITARY MEDICINE

The three scheduled meetings of the Section on Military Medicine were held, as programmed on the afternoons of June 4 5, and 6, in Room 1, 2nd Floor, Coliseum All authors and discussants were present and appeared as listed in the Official Program, with the following exceptions Dr William A Altemeier, Cincinnati, notified the Secretary by telephone on the afternoon of June 3 that he would be unable to be present because he had just operated on a patient whose condition he felt precluded his leaving the city Dr Altemeier forwarded his discussion notes via air mail special delivery, to the Secretary, and the notes were read at the meeting by the Chairman of the Section, Dr Russel V Lee

At the business meeting on June 5 the following were elected to serve as officers for the Section for the 1958 meeting Chairman, Major General Silas B Hays, M C U S Army Washington D C, Vice Chairman Rear Admiral Alphonse McMahon, M C U S N R St Louis Secretary Col Charles H Bramlitt, M C U S A F Washington D C Representative to the Scientific Exhibit, Col Douglas B Kendrick M C, U S Army, Washington, D C, Delegate Dr Charles L Leedham (Colonel, M C, U S Army [Retired]) Cleveland and Alternate Delegate Dr Charles P Campbell, Hackensack, New Jersey

The following resolution was adopted RESOLVED That the Chairman of the Section appoint a committee to meet with appropriate agencies of the American Medical Association to determine the status of the military medical man in the American Medical Association The Chairman appointed the following committee for this purpose Drs I S Ravdin and R A Kern, Philadelphia, and Alphonse McMahon St Louis

SECTION ON MISCELLANEOUS TOPICS

Session on Medical Communication

A Session on Medical Communication was held in the Section on Miscellaneous Topics on Tuesday afternoon, June 4, in the Coliseum

General Elbert De Coursey, Fort Sam Houston, Texas, Chairman, presided over the session A panel discussion on methods of medical communication, including the written word, spoken word, place of the motion picture, preparation and use of lantern slides, and preparation and demonstration of scientific exhibits was presented

Session on Allergy

A Session on Allergy was held in the Section on Miscellaneous Topics on Wednesday afternoon, June 5, in the Coliseum

Drs Carl E Arbesman, Buffalo, and Ethan Allan Brown, Boston, Co-Chairmen presided over the session The papers were presented as listed in the Official Program

Session on Legal Medicine

A Session on Legal Medicine was held in the Section on Miscellaneous Topics on Thursday afternoon, June 6, in the Tudor Room of the Henry Hudson Hotel

Dr Herman A Heise, Milwaukee, Chairman, presided over the session In addition to a paper on Chemical Tests for Intoxication by Dr Heise, a Mock Trial demonstration was presented

SECTION ON NERVOUS AND MENTAL DISEASES

The Section on Nervous and Mental Diseases held three sessions on Tuesday, Wednesday, and Thursday afternoon, June 4, 5, and 6, in the Colonnades Room, Essex House Dr Karl O Von Hagen, Chairman of the Section presided All of the papers were read and discussed as listed in the Official Program

The business meeting of the Section took place on Wednesday afternoon June 5, when the following officers were elected Chairman, Dr Harold C Voris, Chicago, Vice Chairman, Dr Paul H Hoch, New York, Secretary, Dr Adolph L Sahs, Iowa City, Delegate, Dr Francis M Forster, Washington, D C, Representative to the Scientific Exhibit, Dr Benjamin Boshes, Chicago

SECTION ON OBSTETRICS AND GYNECOLOGY

The Section on Obstetrics and Gynecology met in the Ballroom of the Henry Hudson Hotel on Wednesday, Thursday, and Friday morning, June 5, 6 and 7 On Thursday it met jointly with the Section on Pediatrics The papers and panel discussions were presented as listed in the Official Program

The business meeting was held on Friday morning when the following officers were elected Chairman, Dr Woodward D Beacham, New Orleans, Vice-Chairman, Dr Curtis J Lund, Rochester, N Y, Secretary, Dr Keith P Russell, Los Angeles, Delegate Dr Ralph E Campbell, Madison, Wis, and Representative to the Scientific Exhibit, Dr Frederick H Falls, River Forest Ill

SECTION ON OPHTHALMOLOGY

The Section on Ophthalmology held its meetings on Wednesday, Thursday, and Friday morning, June 5, 6 and 7, in the Ballroom of the Park Sheraton Hotel The Chairman, Dr Algernon B Reese, New York, presided over the meetings, and all of the papers were read and discussed as listed in the Official Program

At the meeting of the executive session of the Section on Thursday, June 6, the following actions were taken

The minutes of the 1956 meeting were approved as published in THE JOURNAL of the A M A The Secretary, Dr Harold G Scheie, read a report on the present status of the Section on Ophthalmology, Dr John S McGavic read a supplementary report on the American Board of Ophthalmology, and Dr Parker Heath read the report of the Knapp Testimonial Fund Committee The reports of the following representatives from the Section were accepted

American Board of Ophthalmology
Committee on National Registry of Ophthalmic Pathology
Committee on Scientific Exhibit
Committee on Museum of Ophthalmic History
Committee on National Conference of Medical Nomenclature
American College of Surgeons Board of Governors
Committee on American Orthoptic Council
Lucian Howe Fund
Committee on Research in Ophthalmology and Blindness
Delegate to Pan American Congress of Ophthalmology
Committee on Civil Defense
Committee on Eye Banks
Delegate to House of Delegates
Program Committee

The Section voted to table the report of the representatives to the Committee on Optics and Visual Physiology for further study

Dr Charles E Jaeckle proposed that the Section extend a vote of thanks to Dr William L Benedict for all his services to the Section This was unanimously approved, and a standing ovation was extended to Dr Benedict

Committee members and Section representatives were appointed or reappointed as follows Dr M Luther Kauffman reappointed to American Committee on Optics and Visual Physiology for a period of three years, Dr Algernon B Reese reappointed to Committee on National Registry of Ophthalmic Pathology, Drs Burton Chance, Hans Barkan, and Frederick C Cordes reappointed to the Committee on National Conference of Medical Nomenclature, Dr John McLeod appointed to the Committee on American Orthoptic Council for a period of three years, Drs A D Ruedemann Sr and Michael J Hogan reappointed to the Committee for Research in Ophthalmology and Blindness, Drs William A Mann, P Robb McDonald Warren A Wilson, and Charles E Jaeckle appointed to the Committee on Civil Defense, Drs Ramon Castroviejo and Phinizy Calhoun appointed to the Committee on Eye Banks Drs Alson E Braley, Ralph W Danielson, George M Haik Wendall C Irvine, John L Matthews, W Howard Morrison C Wilbur Rucker, and Frederick H Theodore reappointed to the Program Committee for a period of three years, Dr James H Allen reappointed as delegate to Pan American Congress of Ophthalmology, and Drs Derrick Vail and W Guernsey Frey as Delegate and Alternate Delegate, respectively, to the International Federation of Ophthalmological Societies

The Section nominated three members Drs A D Ruedemann Sr, S Rodman Irvine, and Webb P Chamberlain Jr for selection of one to serve on the Board of Governors of the American College of Surgeons for the term 1958 to 1961, and nominated three members, Drs Arthur Gerard DeVoe, Kenneth L Roper, and Angus L MacLean, for selection of one by the Board of Regents to serve on the Advisory Council for Ophthalmology, American College of Surgeons

The Executive Committee recommended the adoption of a report submitted by the senior trustee of the Herman Knapp Fund, Parker Heath, that the present number of trustees be increased to three members, the existing two members to elect the third This was adopted by the Section

The Nominating Committee submitted the name of Dr John McGavic to be representative to the American Board of Ophthalmology for a four-year term from 1957 to 1961 This was approved by the Section

Members of the Committee on Award of Knapp Medal were elected as follows Drs Frederick A Davis Chairman, C Wilbur Rucker, and Phinizy Calhoun

The following officers of the Section were elected Chairman Dr Dohrmann K Pischel, San Francisco and Vice-Chairman Dr Ralph W Danielson, Denver for the ensuing year Secretary Dr Harold G Scheie Philadelphia for a three year term, Delegate, Dr Ralph O Rychener Memphis, and Alternate Delegate, Dr Harvey E Thorpe, Pittsburgh, for a two-year term beginning in January, 1957

The Prize in Ophthalmology was awarded in absentia to Dr William L Benedict Rochester Minn, by the Chairman, Dr Reese

The Knapp Medal was awarded to Drs Goodwin Breinin and Moldaver of New York Dr Harold Falls presented the award to the senior author, Dr Breinin

At the executive session on Friday, June 7, Dr Ralph O Rychener Memphis, reported on the actions of the House of Delegates, and Dr Frank W. Newell reported on the Scientific Exhibit The $250 prize for the best exhibit was awarded to Dr David Volk of Western Reserve University School of Medicine, Cleveland, for his exhibit on Conoid Ophthalmic Lenses An Original Development in Subnormal Vision Aids Dr Newell reported that this exhibit also received a Certificate of Merit from the Committee on Awards of the Council on Scientific Assembly and that a Certificate of Merit was also awarded to the exhibit on Precancerous Melanosis of the Conjunctiva by Drs Algernon B Reese and Bradley R Straatsma of the Institute of Ophthalmology

SECTION ON ORTHOPEDIC SURGERY

The meetings of the Section on Orthopedic Surgery were held on Wednesday, Thursday, and Friday, June 5 6, and 7 in the Coliseum On Friday morning the Section met jointly with the Section on Physical Medicine

At the business meeting on Thursday morning, the Section voted to establish the position of Assistant Secretary The following officers were elected Chairman, Dr Frederick R Thompson New York, Vice-Chairman, Dr Lenox Baker, Durham N C, Secretary Dr H Herman Young Rochester, Minn Assistant Secretary, Dr J Vernon Luck Los Angeles, Delegate Dr H Relton McCarroll St Louis, and Representative to the Scientific Exhibit, Dr James I Kendrick, Cleveland

SECTION ON PATHOLOGY AND PHYSIOLOGY

The meetings of the Section on Pathology and Physiology were held on Wednesday Thursday, and Friday mornings, June 5, 6, and 7, in the Coliseum, the last meeting being a joint one with the Section on Gastroenterology and Proctology

At the business meeting on Thursday, the following officers were elected Chairman, Dr Edwin F Hirsch, Chicago, Vice-Chairman Dr Thomas M Peery, Washington, D C, Secretary Dr Hugh A Edmondson, Los Angeles, Delegate, Dr Lall G Montgomery, Muncie, Ind and Representative to the Scientific Exhibit, Dr Samuel A Levinson, Chicago

SECTION ON PEDIATRICS

The Section on Pediatrics held meetings on Tuesday and Wednesday afternoons June 4 and 5 in the Terrace Room of the Plaza Hotel The Tuesday session was a joint meeting with the Section on Radiology On Thursday morning it met jointly with the Section on Obstetrics and Gynecology in the Ballroom of the Henry Hudson Hotel

At the business meeting on June 5, the following officers were elected Chairman, Dr George M Wheatley, New York Vice-Chairman, Dr Harry F Dietrich Beverly Hills Calif, Secretary, Dr Wyman C C Cole Sr, Detroit, Delegate, Dr Woodruff L Crawford Rockford, Ill, and Representative to the Scientific Exhibit, Dr F Thomas Mitchell Memphis Tenn

SECTION ON PHYSICAL MEDICINE

The meetings of the Section on Physical Medicine were held on Wednesday and Thursday morning, June 5 and 6, in the Forum Room, the Park Sheraton Hotel, and on Friday morning, June 7, jointly with the Section on Orthopedic Surgery in the Coliseum The Chairman Dr Louis B Newman, presided and all papers were read and discussed as listed in the Official Program

At the business meeting on Thursday the following officers were elected Chairman, Dr Miland E Knapp Minneapolis, Vice-Chairman, Dr Arthur L Watkins, Boston, Secretary Dr Earl C Elkins, Rochester, Minn, Delegate, Dr Walter J Zeiter Cleveland, and Representative to the Scientific Exhibit, Dr Harold Dinken, Denver

SECTION ON PREVENTIVE MEDICINE

The Section on Preventive Medicine met on Wednesday, Thursday, and Friday morning, June 5 6, and 7, in the Coliseum On Wednesday morning, the Section met jointly with the American Academy of Occupational Medicine, on Thursday morning with the American Association of Public Health Physicians, and on Friday morning with the Aero Medical Association

The following officers were elected Chairman, Dr Bruce Underwood, Washington, D C Vice-Chairman, Dr Robert A Kehoe, Cincinnati Secretary, Dr Frank Princi, Cincinnati, Delegate Dr Rutherford T Johnstone, Los Angeles, and Representative to the Scientific Exhibit Dr Paul A Davis, Akron, Ohio

SECTION ON RADIOLOGY

The Section on Radiology held its meetings on Tuesday afternoon, June 4, jointly with the Section on Pediatrics in the Terrace Room, Plaza Hotel, on Wednesday afternoon, June 5, in the Coliseum, and on Thursday afternoon, June 6, jointly with the Section on Diseases of the Chest in the Ballroom of the Henry Hudson Hotel

All papers and discussions were presented as listed in the Official Program, with the exception of the discussion of the paper by Dr George Cooper Jr Dr McLemore Birdsong of Charlottesville, Va, was scheduled to discuss the paper, but he was ill and could not attend the meeting

At the business meeting on Wednesday June 5, the following officers were elected Chairman, Dr Wendell G Scott, St Louis, Vice-Chairman, Dr William W Bryan, Atlanta, Ga, and Representative to the Scientific Exhibit, Dr Richard H Chamberlain, Philadelphia for the ensuing year, Secretary, Dr Traian Leucutia, Detroit, for a three-year term, Delegate Dr Eugene P Pendergrass, Philadelphia, and Alternate Delegate, Dr Earl R Miller, San Francisco, for a two-year term

SECTION ON SURGERY, GENERAL AND ABDOMINAL

The Section on Surgery, General and Abdominal, held its meetings on Tuesday, Wednesday, and Thursday afternoon, June 4, 5, and 6, in the Coliseum The papers and discussions were presented as listed in the Official Program, with the exception of the paper by Dr Ernest E Arnheim, New York Unfortunately he was in an automobile accident enroute to the meeting

At the business meeting on Wednesday, the following officers were elected Chairman, Dr Frank L Gerbode, San Francisco, Vice-Chairman Dr Charles G Child III Boston, Secretary, Dr Gustaf E Lindskog, New Haven Conn, Delegate, Dr Grover C Penberthy, Detroit, Representative to the Scientific Exhibit Dr John H Mulholland, New York, all for the ensuing year Dr Robert M Zollinger, Columbus Ohio, was elected to membership on the American Board of Surgery, and Dr Robert R Shaw, Dallas, Texas, to membership on the American Board of Thoracic Surgery for six-year terms

SECTION ON UROLOGY

The Section on Urology met on Wednesday Thursday, and Friday morning, June 5, 6 and 7, in the Colonnades Room of the Essex House the session on Friday being a joint meeting with the Section on General Practice All of the papers and discussions were presented as listed in the Official Program

The John H Morrissey award was presented to Drs Sam G Jameson James O Cooper, and J Schuler McKinney, El Dorado, Ark, for their exhibit on Pediatric Urology

At the business meeting on Thursday, the Section voted to establish the position of Assistant Secretary and Assistant Representative to the Scientific Exhibit The following officers were elected Chairman, Dr Roger W Barnes Los Angeles, Vice-

Chairman, Dr Dean Parker, Seattle, Secretary, Dr Thomas A Morrissey, New York Assistant Secretary, Dr Robert Lich, Louisville, Ky, for the ensuing year, Delegate, Dr Jay J Crane, Los Angeles, Alternate Delegate, Dr Earl E Ewert, Boston, and Representative to the Scientific Exhibit, Dr Milton M Coplan Miami, Fla, for two years, and Dr E F Poutasse, Cleveland, as Assistant Representative to the Scientific Exhibit for the ensuing year

SCOUTS JOIN IN WAR ON POISONINGS

Educating the public on the need for preventing accidental poisonings can be a responsibility shared by physicians, hospitals, industry, and local citizens In recent months, countless poison control centers have sprung up throughout the country A good sign in the prevention of poisonings is the fact that persons other than physicians have become interested in promoting these projects

To publicize the educational function of its newly opened poison information center, the Los Angeles Childrens Hospital teamed up with Boy Scouts from this area and the Union Oil Company of California in presenting an exhibit at the annual Scout-o-Rama held on June 8, in the Los Angeles Memorial Coliseum Staffed by Mrs Claire Barton, a registered nurse in charge of the center, and Scout Troop number 86, the exhibit stressed three important messages prevention recognition of poisonous substances, and instructions on what to do when poison has been orally ingested A pamphlet also was distributed to 6,500 persons emphasizing the common household poisons, adequate prevention, and the importance of contacting a physician before using an antidote Nearly 75,000 parents and friends of Scouts attended the Scout-o-Rama

Pointing out the danger of poisoning from common household products such as fingernail polish, aspirin, and perfumes, are members of Troop 86 of the Los Angeles Boy Scouts at an exhibit on poison information center during Scout-o-Rama which took place on June 8 at the Los Angeles Memorial Coliseum

This program is in line with a recent stepped-up activity of the A M A Committee on Toxicology, which has been investigating various means of improving public education on chemical safety The Committee's exhibit on accidental poisonings is being shown at a number of state and county health fairs Also available from the Association is a radio transcription on accidental poisonings for use over local radio stations

A M A ACTS TO COMBAT INFLUENZA EPIDEMIC

The American Medical Association has launched a nationwide preparedness program to combat a possible outbreak of Asiatic influenza in the United States Working closely with Surgeon General Leroy E Burney and the U S Public Health Service in Washington, D C, the A M A has approved a plan which will alert the nation's practicing physicians to the dangers of a possible flu outbreak

"The epidemic may never strike in this country," reports Dr David B Allman, Atlantic City, N J, A M A President, "but the American Medical Association is anxious to have practicing physicians mobilized and alerted in case an outbreak does occur Thousands of persons have been stricken with the disease in the Far East during the last few weeks and it is only good medicine to deal in probabilities now when we have the time In that way, the American people will be best served from a medical standpoint" Dr Allman stresses the fact that there is no immediate cause for alarm

The A M A Board of Trustees has authorized a special A M A Committee on Influenza to handle the project Chairman of the Committee is Dr Harold C Lueth, of Evanston, Ill, who has been serving for some time as Chairman of the A M A Committee on Civil Defense The Committee on Influenza plans to "Inform all physicians, through state and county medical societies, on how to deal with any Asiatic influenza epidemic, urge state and county medical societies to prepare and develop stand-by programs and plans to cope with any epidemic should it occur, formulate plans at the national level to utilize all medical personnel, regardless of type of practice, in time of an influenza emergency, and coordinate state and local programs with public health agencies and health departments"

The A M A and the U S Public Health Service plan to carry on a cooperative public educational program with the help of newspapers and television and radio stations The public will be given information about the particular virus—type A Far East strain—which causes the disease and how best to treat it when it strikes The influenza caused by the new virus has been relatively mild, marked by a three-to four day period of fever and other typical symptoms of influenza Several pharmaceutical manufacturers are now producing a vaccine to combat the Far East strain No verified deaths from the disease have been reported in the United States but it is estimated that the attack rate would run between 15 and 20% of the population of any city where the disease reached epidemic proportions

Postgraduate Courses for Physicians

Compiled by the Council on Medical Education and Hospitals for the Period Sept 1, 1957, to Aug 31, 1958

The data in the following list of postgraduate courses have been compiled by the staff under the supervision of Dr Glen R Shepherd, Assistant Secretary of the Council on Medical Education and Hospitals, with the clerical assistance of Miss Eileen O Brien The Council desires to express appreciation to the officers of the medical schools hospitals and medical societies who have cooperated in furnishing the information essential to the preparation of this report

Edward L Turner, M.D , Secretary
Council on Medical Education and Hospitals

INTRODUCTION

The third annual listing of postgraduate courses for physicians appears in the following pages of THE JOURNAL This listing is for the period Sept 1, 1957, to Aug 31, 1958 The annual lists replace the semiannual lists that appeared previously

Postgraduate medical education courses consist of planned activities for doctors of medicine intended to refresh practicing physicians in the various aspects of their basic medical education, to provide information on new developments in medicine, and to stimulate further educational efforts by the participants Such courses are not designed to provide the lengthy intensive education required for specialist training and thus they may not lead either to credit toward graduate degrees or to specialty board certification These are in the field of graduate medical education and usually consist of residency training or fellowships Postgraduate courses are shorter than graduate education programs

The Council on Medical Education and Hospitals has studied the field of postgraduate medical education for several years For more than a year, its *ad hoc* Advisory Committee on Postgraduate Medical Education has studied ways in which the Council can be of greatest assistance in the further development of this part of medical education As a first step in such a course of action recommended by the Advisory Committee and endorsed by the Council, the House of Delegates of the American Medical Association adopted in June, 1957, a document entitled A Guide Regarding Objectives and Basic Principles of Postgraduate Medical Education Programs ' It should be of interest to all who are actively interested in this field A copy may be obtained on request to the Council on Medical Education and Hospitals, American Medical Association, 535 N Dearborn St , Chicago 10

This list of postgraduate courses was prepared from the unappraised and unevaluated replies to Council questionnaires by American medical schools, the hospitals having approved internship and residency training programs, and the various national, state, and specialty medical societies This list is printed simply to provide for those physicians seeking postgraduate courses a point of departure through which further information can be obtained by writing to the institution or organization listed under Location Such inquiries should be made before traveling to any course listed, because dates, time arrangements, and fees are subject to change Courses for which there is insufficient registration may be canceled Such inquiry of the sponsor is especially urged about courses scheduled for 1958, on which final information may not have been available to the sponsor at the time this list was prepared

Though the educational values of medical society meetings and conventions as well as hospital staff and departmental meetings can be very real and worthwhile, such meetings are not usually here listed as postgraduate courses Lists of society meetings are to be found monthly elsewhere in THE JOURNAL

Many of the courses listed have co sponsors to whom specific credit cannot be given because of space limitations It is expected that the institution or organization sponsoring the course has provided such co sponsor recognition to its registrants, for such organizations as the American and state heart associations, the American and state cancer societies, the National Foundation for Infantile Paralysis and its state chapters, the academies of general practice, other medical societies, and the various state boards of health are active and important in the field of postgraduate medical education

In the following list under each category, the order of arrangement of the courses is alphabetically first by states, second by cities within states third by the institutions and organizations within the cities, and last by date of course where several are offered by the same institution or organization

Although the list may indicate that a course is designed primarily for specialists in that category, many such courses are open to any physician so specific inquiry should be made of the institution listed

One of the categories in this list has a special use in addition to its usual denotation In the General Practice category are listed those courses having subjects embracing several fields, such as a course on the management of mass casualties or a course on both pediatrics and obstetrics

KEY

Designed
G—Primarily for physicians in general practice and part time specialty practice
S—Primarily for physicians in full time specialty practice
B—For both of above

Type
A—Time by arrangement
BC—Brief course less than five days regardless of hours per day
BCI—Brief course intermittent
SC—Short course five or more days
SCI—Short course intermittent
CC—Circuit course (same course given at different locations)
MT—Medical traineeship*
HS(TV)—Home study by television
HS(R)—Home study by radio
HS(AV)—Home study by audiovisual kit
HS(C)—Home study by correspondence or assigned reading
O—Other

Time Arrangement
C—Continuous or concentrated (e g as every day for five days)
I—Intermittent (e g every Thursday for six weeks)

Methods of Instruction
AV—Audiovisual aids (movies slides models)
Cad—Cadaver demonstration or dissection
Dem—Demonstration other than of patients
EPP—Enrollee performs procedure
O—Open questions
Lab—Laboratory work
Lec—Lecture
LC—Live clinic
Pan—Panel
Pt Dem—Patient demonstration
Sem—Seminar
Sur—Operative surgery
TV—Television
WR—Ward rounds
MT—Medical traineeship*

* Medical traineeship is a residency type experience in hospital clinic or school with participation in residents conferences and ward rounds but usually without patient responsibility This specially arranged experience usually lasts from two weeks to less than a year Neither housing nor formal credit is provided *Traineeships* usually do not involve night or emergency room duty

Simmons, John Walter, Simpson, Kan, Kansas Medical College, Medical Department of Washburn College, Topeka, 1897, died May 9, aged 85

Steinmetz, Charles Gordon Jr, Philadelphia, Medico-Chirurgical College of Philadelphia, 1910, an associate member of the American Medical Association, veteran of World War I, served on the staffs of Presbyterian and Woman's hospitals, died in the Jefferson Hospital May 28, aged 69

Thomson, Thomas Leonard ⊕ Torrington, Conn, Hahnemann Medical College and Hospital of Philadelphia, 1901, past-president of the Torrington and Litchfield County Medical societies, formerly vice-president of the Connecticut State Medical Society, associated with the Charlotte Hungerford Hospital, where he died April 18, aged 84, of bronchopneumonia and carcinoma of the lungs

Timerman, Arthur Rood ⊕ St Joseph, Mo, Louisville (Ky) Medical College, 1894, past-president of the Buchanan County Medical Society, died in Ocala, Fla, May 18, aged 83

FOREIGN LETTERS

AUSTRIA

Undescended Testis —At the meeting of the Vienna Society for Pediatrics, in May, R Jonas discussed the cause, diagnosis, and treatment of cryptorchism False cryptorchism is a simple arrest of testicular development Spontaneous descent of the testis may occur between the ages of 12 and 17 years in patients with this condition This descent is explained by the excretion of gonadotropin during puberty True cryptorchism is a genetic disturbance, frequently associated with other malformations such as delayed fetal development of the sex organs which results in intersexual manifestations A boy with false cryptorchism should be operated on in the 12th to 16th year and with true cryptorchism in the 6th to 8th year so that the pathologically changed testis can develop in the right place An exact diagnosis is most important Association with hernia, inguinal pains, such rare complications as torsion of the spermatic cord, and every form of ectopia are also indications for operation

Tuberculosis of the Bones and Joints —At the same meeting, O Ruziczka said that he had treated, with tuberculostatic drugs, 48 children aged from infancy to 14 years who had tuberculosis of the bones and joints Treatment with these drugs can cure patients with the proliferative-granulating form of the disease if it is diagnosed and treated early The regenerative power of the bones is good in this age group Removal of the focus and follow-up after tuberculostatic treatment are necessary in patients with larger necrotic foci associated with caseation Of the 48 children, 13 were cured by general treatment and tuberculostatic drugs No recurrence was seen in follow-up examinations up to nine years later In 13 children removal of the focus was performed, and 3 others were given local antibiotic injections Tuberculous meningitis occurring simultaneously caused death in two patients Patients with uncomplicated synovial tuberculosis also showed good results with conservative tuberculostatic treatment Pyarthrosis must also be locally treated with the aid of injections or, after operation, with tuberculostatic drugs Tuberculous fistulas may close after a favorable influence on the basic osseous process In three patients they had remained closed for eight or nine years when last seen If they do not close, they must be excised Old proved methods of treatment as well as new possibilities of treatment have improved the prognosis of infantile tuberculosis of the bones and joints and shortened the duration of treatment A cure can be obtained with restoration of normal position, form, and function

CANADA

Tax Relief on Pension Contributions —For some time, several of the professional associations of Canada have been requesting the Minister of Finance to defer taxes on pension contributions by the self employed Professional men, particularly those in private medical practice, were concerned with the problem of no tax relief on money set aside for a pension plan to provide for their old age, whereas employees in firms with pension plans enjoyed tax relief on such contributions The minister of finance has now relented and permitted new arrangements closely in line with the recommendations of the Canadian Medical Association From next January, self-employed taxpayers may claim as deductions from earned incomes sums up to 10% of their income contributed to approved annuities or other specified forms of retirement funds Employed taxpayers who are already participating in a pension plan may supplement their present coverage by a separate annuity contract and may deduct personal contributions The way is also open for professional organizations such as the Canadian Medical Association to provide a trusteed fund for their members out of which an immediate annuity may be purchased at the age of retirement

Aminopterin Sodium as an Abortifacient —Bourne and co-workers (*Canadian Medical Association Journal*) report a case in which grave illness was produced by the attempts of a pregnant woman to abort herself by taking aminopterin sodium She bought 100 tablets and took 8 (4 mg) on one day, 8 the next day, and 4 the next day She had thus ingested a total of 20 tablets or 10 mg of aminopterin, according to her own statement, but she may have taken more Next day she developed a severe sore throat and later a diffuse erythema of the entire face with swelling and vesicle formation and an inflammatory reaction of the lips and gums The entire oral cavity and pharynx were tender and the patient was in severe distress When she was admitted to the hospital, abortion was taking place and the toxic effects of the drug were evident in lesions of the face, mouth, chest, and abdominal skin, but there was never any evidence of suppression of hematopoiesis She also suffered from temporary loss of hair Immediately after admission, treatment with a specific antidote, citrovorum factor (0 5 mg twice a day) was started The patient was also given penicillin and streptomycin Her symptoms subsided slowly, and it is thought that administration of the antidote may have saved the patient's life or at least hastened recovery

Control of Medical Care —At the meeting of the Canadian Public Health Association in Toronto in May, Dr Matthews of the Saskatchewan Department of Health discussed the control of the quality of medical care He noted that in the Health Insurance Plan of Greater New York, control is accomplished by the

---

The items in these letters are contributed by regular correspondents in the various foreign countries

insurance agency and involves the use of a closed panel of physicians Dr Matthews believes that it would be better if controls were exercised by the physicians themselves In Canada, more confidence is placed on the results of examination of physicians by provincial licensing authorities and by the Medical Council of Canada If insurance agencies were to make a further distinction between physicians fit to practice and those unfit, they would not necessarily raise the standards of those they excluded but simply segregate them from their fellows In any health insurance plan, a probationary period for a participating physician is of value If every insurance agency were to set its own standards, confusion would result It is important that administrators of all insurance plans cooperate with the medical profession in insuring standards and indicating to the profession where such standards need tightening up Few evaluations of medical care have been made in Canada, and those few were usually made to solve a particular problem rather than to be on a continuing basis Administrators of hospital insurance plans tend not to care whether their clients are treated in hospitals giving good quality care With the forthcoming extension of hospital insurance in Canada, it would be natural to expect that payments by the government would be limited to hospitals known to maintain good standards of care Good results have been obtained with prepaid medical care in a Saskatchewan area in which an active assessment committee was elected by the medical profession of the area and granted broad powers by the district medical society This assessment committee had done a great deal of good in raising standards

The cost of medical care in a well-known prepaid plan in Ontario was analyzed by another speaker who showed that between 1930 and 1953, whereas personal expenditures in Canada had increased substantially for tobacco, alcohol, and transportation, expenditures on personal medical care had not increased relatively Between 1946 and 1953, the income of Canadian physicians in private practice has remained at a constant 1% of the total assessed income of all the taxpayers in Canada Other statistics prove that the net annual income of physicians in Canada between 1950 and 1954 increased roughly parallel with the average weekly income of industrial workers It has certainly not increased beyond that Hence, over these years, physicians are relatively as well off as industrial workers In the plan analyzed in Ontario, annual costs per 1,000 participants and utilization rates have increased steadily from 1949 to 1956 The utilization rate has increased from 2,300 to nearly 3,900 persons per year The increase in costs appears to be due to increased services, increases in fee schedules, and increases in the proportion of expensive services, mainly surgical Although it is unlikely that medical need has increased in the last few years among the population covered by this plan, it would seem that the more prosperous and leisured a society becomes, the more it worries about its health *The situation is reasonable* if the insurance plan is a voluntary one, otherwise there is a danger that excessive demands will be made on the medical profession without an increase in income, as has happened in the United Kingdom

This speaker also described a system developed in this health plan for sharing costs and number of services between physicians in the same county Where a physician consistently shows high average costs and a high rate of service, the amount payable to him may be subject to control, but few physicians in Ontario have been placed on this control system A general practitioner remarked that there will always be variations in costs of medical care from patient to patient and from physician to physician He called for an analysis of physicians expenses, an increasing item in the provision of medical care He also said that the profession must either give leadership or like what it gets in the health insurance plan

Hospital Bed Requirements—The Canadian Public Health Association discussed planning for hospital bed requirements at its annual meeting Mr John Osborne of the Ottawa Department of National Health and Welfare said there was a great variation in hospital beds per 1,000 population among Canadian provinces In post-war surveys it was found that the number of beds for acutely ill patients varied between 4 6 and 7 5 and for chronically ill patients between 1 5 and 2 0 Mr Osborne placed little faith in the idea of setting a fixed ratio of beds to population Two of the main provinces in Canada (Ontario and Quebec) receive many immigrants and therefore tend to be constantly short of beds, particularly since many of the immigrants come from areas of Europe where hospitals have a high utilization rate It is also paradoxical that in some provinces with a low bed capacity there is also a low utilization rate, even in spite of long stay and insurance coverage All this means that it is impossible to say, when a hospital insurance plan is started in a province, that the figure for hospital beds should be the same as in adjacent provinces with the same type of plan Hospital planning in Canada should include planning for domiciliary care, otherwise patients who could be treated at home will stay in the hospital Under the prospective provincial hospital plans, more adequate attention will probably be given to general planning, and provision of facilities for active, chronic, convalescent, rehabilitative, and other beds will probably be more balanced

Chronic Diseases—At the same meeting, speakers emphasized that it was time to stop trying to define chronic diseases narrowly and to imagine that physicians treat two separate entities—acute and chronic disease Throughout the course of the chronic disease, some type of treatment can always be given The difficult but essential problem to be overcome is the integration of treatment of chronic diseases with other aspects in the social and economic field The services for chronic diseases are provided in a wide range of facilities, including the general hospital, special hospital, convalescent home, nursing home, rehabilitation center, physician's office, and the patient's home Because it is necessary to insure that care is being provided at the correct level, the needs of each patient must be assessed and reassessed from time to time A controversy still exists as to whether separate institutions are needed for chronic diseases or whether these diseases should be treated in a general hospital Canada will probably adopt a compromise according to the area, sometimes using the wing of a general hospital and sometimes separate facilities It is also essential that there be a flow of patients between the various levels of care, this implies cooperation with other agencies Hospital admission policy must be coordinated with a satisfactory discharge and domiciliary care policy

Dr Charron of Ottawa suggested classification of patients with chronic disease for admission as those with a favorable rehabilitative prognosis, those with a poorer prognosis, those seeking alleviation by hospital care, and those in a terminal state Another problem is that of determining whether the authority for admission should be placed with the patient's physician or with a screening committee acting in close consultation with the physician The criterion for admission of a chronically ill patient is that active treatment be required The discharge arrangements are the responsibility of social service workers and should be anticipated when the patient's admission is arranged At present, the weakest link in the program in Canada is the social services, where a shortage of all classes of trained personnel exists Any research program on chronic diseases should include research into planning and administration and into the prevention of disease

Health Education—At the same meeting, Dr Gilbert said that health education is a basic function of all health departments It should also be the main objective of all voluntary health agencies and the basis of all activities of health workers The most efficient method of carrying it out is by personal contact, but in order to reach the whole population, mass media must be used even if such education is more superficial The health educator should be specially trained to assist other members of the health team Health educators might carry out locally a continuous health education program, but materials for this program might best be prepared and distributed at the national level The present one-year course for health educators is probably inadequate, and the University of Toronto is considering a two-year course leading to a degree

FRANCE

Antihyaluronidase Serum and Cancer—At a meeting of the Academy of Sciences in March, A Lacassagne and co-workers stated that they attributed the growth and invasiveness of mammary cancer in mice to the production of hyaluronidase They tried to stop this proliferation with antihyaluronidase serum The natural barrier of the connective tissue was thus strengthened The authors propose to try this serum as a palliative treatment of some cancers in human beings

Housewives' Eczema—At the February meeting of the French Society of Allergy, Coulant and Lopes stated that water eczema is not a matter of simple allergy to water or to any household product but that such products localize the disorders on the hands and forearms The cause is a parasitic infiltration When the parasitosis is cured, the eczema disappears and housewives may go on with their housework even if the cutaneous test with the localizing products remains positive

Cardiac Catheterization—J Facquet and co workers at the International Cardiologic Week reported that catheterization of the left side of the heart can be accomplished without significant risk through a bronchus under bronchoscopic control This method is not associated with any pleuropulmonary complication and is painless A simple puncture of the auricle has been made in 200 patients This makes it possible to make auricular tracings and to measure intra auricular pressures The procedure is chiefly useful in studying mitral valvular diseases, in patients in whom catheterization of the right side of the heart has failed Another advantage of the method is that it can be repeated several times The tracings must be interpreted with caution Allison and Linden's coefficient, bringing into account the zero reading of the pressure at the moment when the mitral valve shuts and opens is the best way to evaluate the pressure The pressure in the left auricle and ventricle can be measured simultaneously

Allergic Character of Peptic Ulcer—Iagov and Cosmulesco (*Archives des maladies de l'appareil digestif et de la nutrition*, February, 1957) stated that in guinea pigs sensitized to human serum or an extract of corn starch, the antigen injected under the gastric serosa gave a congestive zone at the point of injection Among 28 patients with peptic ulcers, only one did *not* respond to one or several tests Of 85 such patients, 31 showed a gastric eosinophilia It cannot be said whether allergy occurs before or after the ulcer is formed

Hypogalactia—Ruzicic (*Concours médical*, Feb 23, 1957) proposes to use the baby's thirst to measure hypogalactia in the mother The baby is placed at the breast, and after nursing he is given as much water as he wants The quantity of water imbibed is measured, and the total quantity thus taken in 24 hours is calculated The author believes that the quantity of water taken after nursing corresponds to the deficit of the mother's milk If the amount of water drunk is less than a third of the optimal quantity of milk the child should get, the child is merely observed, but if the amount is more than half of the optimal quantity, artificial feeding should be started

INDIA

Kwashiorkor—Subrahmanyan and co-workers (*Indian J Pediat* 24 112, 1957) state that kwashiorkor is common among malnourished children of the lower income groups in India It is caused primarily by a deficiency of protein in the diet, although vitamin deficiencies may be contributing factors Investigations carried out in the Central Food Technological Research Institute at Mysore have shown that a low cost protein food made from low-fat groundnut flour (60 parts), Bengal gram dhal (20 parts), and skim milk powder (20 parts) and fortified with calcium and vitamins is effective in the treatment of protein malnutrition The authors reported three patients with kwashiorkor treated with this low-cost protein food The patients were children aged 2 to 3 years Their diet survey revealed that the daily intake of calories and proteins was highly inadequate over a period of one or two years There was no history of any previous illness Generalized edema was present in all patients All had had diarrhea for 15 to 30 days Two showed mild angular stomatitis, and discoloration of the hair was present in two One showed crazy-pavement dermatosis over the legs and forearms, and the other two showed hyperpigmentation with dermatitis over the thighs and hips The serum protein and serum albumin levels were very low, but the serum globulin level was normal Routine hospital treatment for diarrhea and edema given for two days was of no avail Later the low-cost protein food was given in four divided doses in the form of gruel sweetened with 2 or 3 teaspoonfuls of sugar, the daily dose being 4 or 5 oz (113 3 or 141 7 Gm) One ounce (28 Gm) of this food supplied 11 5 Gm of protein, 210 mg of calcium, 230 mg of phosphorus, 0 4 mg of thiamine, 1 0 mg of riboflavin, 4 0 mg of niacin, 857 I U of vitamin A, and 71 I U of vitamin D A marked improvement in the general condition was noticed in 8 to 10 days, with complete disappearance of the edema taking three or four weeks Diarrhea, dermatosis, and hyperpigmentation all disappeared in time The patients were kept in the hospital for six to eight weeks The average loss of weight due to disappearance of edema was 3 lb (1 4 kg), and the total gain at the time of discharge was about 8 lb (3 6 kg)

Struma Lymphomatosa —Sathe and Sirsat (*Journal of Postgraduate Medicine*, April, 1957) reported 10 cases of thyroid glands removed surgically which on histological examination showed evidence of struma lymphomatosa Six of the cases were diagnosed clinically as malignant goiter The ages of the patients varied from 35 to 67 years, 7 were female and 3 male The duration of the disease ranged from one week to two years The patients complained of swelling in the region of the thyroid and symptoms of pressure on the trachea or esophagus Pain was present in three patients The enlargement was bilateral in all but one None showed signs of thyrotoxicosis Total thyroidectomy was performed on two and subtotal on eight patients In one patient, in spite of operative removal of the thyroid, relief from pressure symptoms was not complete and a roentgenogram four months after operation revealed a mass in the retrotracheal region In this patient there was postoperative growth and downward extension of the residual struma in the retrotracheal region

Family Planning —A family planning training center was established in Bombay for training physicians, health visitors, and social workers Five grants for opening and maintenance of family planning clinics and two for research on family planning were made by the government A detailed scheme for promoting family planning has been drawn up for the whole country It consists of the opening of government-aided family planning clinics, especially in rural areas, carrying on of publicity for family planning through audiovisual aids, training of medical and auxiliary personnel in family planning, laying down the standards for contraceptives, and undertaking of demographic, medical, and biological research studied

NORWAY

Infectiousness of Tuberculosis —While it is generally assumed that the risk of infection with tuberculosis varies greatly under different conditions, statistical proof of this assumption has seldom been undertaken In a 146-page monograph, Hertzberg and Backer of the Tuberculosis Division of the Oslo public health service have attempted this task They studied some of the 11,179 persons registered as new cases of tuberculosis in Oslo during the 14-year period, 1940 to 1953 In the homes of 2,361 of these persons there were 4,257 children under the age of 15 years Each of these homes was visited, all occupants undergoing tuberculin testing and a radiological examination These home contacts were classified according as they were tuberculin-negative, tuberculin-positive, superinfected (Pirquet reaction increased), or actively tuberculous The patients on whose account the homes were visited were classified in different groups according to the severity of the disease, with cavitation at one extreme and pure hilar adenitis at the other Account was also taken of whether tubercle bacilli were demonstrable by direct microscopy or culture Concomitant cough and sputum were also factors influencing the risk of infection The authors concluded that for children aged 0 to 4 years the risk of infection is three times greater when the patient suffers from cavernous tuberculosis than when he presents pulmonary infiltrations without radiological signs of necrosis It is hoped that these statistical facts may in some degree assist the phthisiologist

Herniation of Nucleus Pulposus —Berg and Kolstad, in *Tidsskrift for den norske lægeforening* for June 15, report a series of 135 patients with herniation of the nucleus pulposus Of these patients 100 were operated on A follow-up examination one to nine years after treatment showed that, in the operated group, 77 had achieved a complete cure with full capacity for work, 16 were improved, and 6 obtained poor results Though in the patients receiving only conservative treatment the condition was less severe, 11 5% obtained poor results, 60% were cured, and 28 5% showed some improvement Myelography was found to be essential to the diagnosis of herniation of the nucleus pulposus Fixation operations are now limited to a partial laminectomy or an archotomy of the adjoining arches The operation was followed in one patient by complete paralysis of both legs Slow but almost complete recovery was effected after conservative treatment

Symposium on Anticoagulants —Prof P Owren (*Nordisk medicin*, May 30, 1957) said that the risk of hemorrhage from anticoagulants was about the same for bishydroxycoumarin and phenindione, being very small in either case, with only about 2% of the patients suffering from this complication He deplored the lack of control groups as a check on the results claimed but he insisted that ethical and legal considerations prevented administration of placebos to patients who believe they are receiving bona fide treatment Dr T Hilden argued on the other hand in favor of control series to provide reliable evidence for or against long-term treatment with anticoagulants With an experience of more than 600 patients given long-term treatment, Owren said that the mortality was between 4 and 6% in the first year, but only 2 5% when the symptoms had lasted less than a year Dr C Bjerkelund gave an account of the 237 patients surviving myocardial infarction who were treated with anticoagulants in the acute stage of the disease While 119 had continued to receive anticoagulant treatment, 118 had not received it, but were kept under observation The relapse rate of infarction was much higher in the latter than in the former group The difference was most marked in the first year of the treatment in patients under the age of 60 Here the relapse rates were respectively 3 and 14% The chance of dying of a new infarct was greater for young than for elderly patients The latter were more liable to progressive cardiac insufficiency—a condition less amenable to anticoagulant treatment than infarction

PORTUGAL

Epileptic Psychosis—D Furtado (*Jornal do Medico,* 1957, no 740, pp 729-740) says that epileptic psychoses assume variable forms—confusional states, psychosomatic types, endogenous types, cyclothymia, and schizophrenia The author even found recurring paranoid episodes with hallucinations in patients with epileptic psychosis From the electroencephalographic viewpoint, interseizure psychosis appeared more frequently in patients with temporal lobe epilepsy, in whom the symptoms are psychomotor or purely psychic Also in centrencephalic epilepsy, with bilateral paroxysmal dysrhythmia, interseizure psychosis may be seen This does not occur in patients with focal epilepsy A strange feature of this condition is the normalization of the epileptic dysrhythmic electroencephalogram during the period of the interseizure psychosis

Herpes Zoster—Bastos Viegas and Cunha Veigas (*Jornal do Médico,* 1957, no 733, pp 327-330) obtained good results in 42 patients with herpes zoster by giving a daily dose of 20 to 60 mg of emetine chloride There were no side-effects When fever or systemic symptoms accompanied the pain and vesicular eruption, antibiotics were also given A prolonged anesthesia of the radicular zone was observed in some patients

TURKEY

Turkish Medical Association Centennial—The Turkish Medical Association was founded in 1856 at the termination of the Crimean war with the cooperation of French and English army surgeons At all times during the past 100 years the changes in the political and social structure of the country have to a high degree been realized by virtue of the activities of physicians devoted to medical and social progress Although a great deal has been accomplished, much remains to be done, especially in medical education The steady increase in population necessitates more physicians, but more and more students are deciding on careers in the fast-growing industries On the average 350 to 400 physicians are graduated annually At present there are 8,172 physicians (7,518 men and 654 women) of whom 4,192 are specialists and 3,980 are general practitioners Of the 8,172 physicians 2,260 or 1 for every 683 persons are located in Istanbul, 734 or 1 for every 1,581 persons in Ankara, and 427 or 1 for every 2,106 persons in Izmir More physicians are needed There are 759 vacancies for the position of staff physician in government hospitals, and 94 more health centers are needed These would require 204 health officers, 234 center physicians, 49 anti-malarial specialists, 33 anti trachoma specialists, 11 anti-venereal specialists, 21 phthisiologists, 104 pharmacists, 462 sanitary inspectors, and 315 nurses and midwives In 1956, 195 physicians, 61 specialists, 109 nurses and midwives, and 51 interns resigned Of 157 districts 28 are without a physician, 77 health centers have a full staff, 81 have only one physician, and 43 have none

The association's report on the financial status of physicians reveals that 80% of the specialists have no bank account worth mentioning, 75% are not home owners or owners of real estate, 16% have a car which they drive themselves, and 1% employ a driver Physicians fees are too low Of the general practitioners 82% have no bank account or property Attention was drawn to the discrepancies in general practitioners fees and salaries accorded engineers, some of whom receive 10 times as much as the physician

UNITED KINGDOM

Duodenal Ulcer in Children—Although duodenal ulcers are known to occur in children, Goldberg (*Brit M J* 1 1500, 1957) states that the incidence is much higher than is generally recognized He reports a series of 20 cases and emphasizes that the clinical findings differ from those observed in adults In the infant the condition is acute, with perforation and hemorrhage being common In the older child the presenting symptom is pain in most cases The location, character, time relation to meals, and relief by drinking milk suggest the diagnosis, but in about half the cases the pain is atypical In children the onset is often acute with severe generalized pain or pain referred to the umbilicus, right hypochondrium, or right iliac fossa Vomiting and pyrexia are often present The clinical findings may resemble those of appendicitis or intestinal obstruction, and, in error, operations are frequently performed for the latter conditions Hematemesis and perforation may occur

During the second phase the history is still atypical, but the symptoms are less acute The abdominal pain is often generalized, central in position, or in the right hypochondrium, and frequently it is not relieved by alkali, food, or vomiting It is often worse at night and may last from a few minutes to several hours Local tenderness may be absent All complications, except malignancy, are the same as in adults Hematemesis is more common than melena Pyloric stenosis occurs in about 25% of the patients and more frequently in older children The fractional test meal is of little help in diagnosis, as it usually shows normal results Even at laparotomy an ulcer can be overlooked, as there is little fibrosis and the outer coat of the duodenum usually appears to be normal The only aid that establishes the diagnosis beyond doubt is a barium meal, although the radiologic demonstration of the niche of a duodenal ulcer in children is difficult because of the rapidity with which the barium passes the duodenal cap With the exception of closure of perforations, the treatment of a duodenal ulcer in childhood and adolescence is medical Stress is an important causative factor

Medical Research Council's Annual Report—According to the report of the Medical Research Council for the year 1955-1956, carcinogens found in tobacco smoke have induced hyperplasia in human fetal lung grown in tissue-culture Poliomyelitis vaccination with the British vaccine has shown that the titers produced against all three types of virus are satisfactory, and experiments with monkeys show that it confers a high degree of immunity to challenge with a virulent strain In children aged 1½ to 9½ years, the attack rate of paralytic poliomyelitis, after vaccination, in 1956-1957, was only 20% of that in unvaccinated children Live attenuated vaccines are under trial

It was shown that a bacterial virus acts by attaching itself to the bacterial cell and injecting its desoxyribonucleic acid, which takes control of its host's synthesizing mechanisms, causing them to produce more viral desoxyribonucleic acid and protein Often bacteria become permanently infected with a phage virus and are able to transmit it to their progeny In work on experimental filariasis, it was shown that microfilariae remained in the lung capillaries during the day and were more generally distributed in the circulating blood at night The antifilarial agent, diethylcarbamazine citrate, acts like an opsonin and is active in the blood stream where the phagocytes are inaccessible Species of Wuchereria similar to the human type have been found in animals, and several species of mosquito are known to be vectors Control, by use of DDT, of the Simulium fly that is the vector of onchocerciasis has been successful The difference between normal and sickle-cell hemoglobins has been shown to be due to one peptide which bears a positive charge in sickle-cell hemoglobin with a pH of 6 4 but is uncharged in normal hemoglobin This difference is due to a valine molecule in the charged peptide and a glutamic acid molecule in the neutral peptide This is the first time that the effects of a single mutation on the chemical structure of a protein have been elucidated It is thought that when the sickle-cell-hemoglobin molecules lose oxygen, they may form fibrillar aggregates which attract one another into a parallel orientation, distorting the cell

Homografts are destroyed unless the graft is between identical twins or members of an inbred strain The power to destroy grafts is lost after irradiation Irradiated mice, normally expected to die, recover when inoculated with marrow which colonizes the irradiated host Under these conditions grafts from other species may survive Leukemic mice have been treated by irradiation to destroy all the blood forming tissue and then have been given a marrow graft from a healthy animal

Obstetrics and the General Practitioner—Although the number of confinements in the hospital is increasing, many women prefer to have their babies at home under the care of the family practitioner or in a local hospital where he has access to beds The National Health Service has done little to encourage domiciliary midwifery, apart from paying the physician a little extra for his services The College of General Practitioners has published a survey of general-practitioner obstetric services, based on 4,277 deliveries conducted by 117 family physicians in the southwest part of England About half these physicians had received postgraduate hospital training in obstetrics, and 90% had been practicing domiciliary obstetrics for more than five years According to the report, the standards are excellent, but this is based on the work of a selected and well-qualified group and does not necessarily reflect the obstetric standards of general practitioners throughout the country Each physician selected for this review averaged 30 obstetric cases a year, about a third being delivered in general-practitioner hospitals and the remainder at home Most of the physicians had diagnostic laboratory and radiologic facilities, and about 67% had access to beds in local hospitals—which is unusual under the National Health Service This does not reflect the facilities generally available to general practitioners for obstetric work The survey is therefore biased in favor of good obstetric care

According to the survey, the perinatal mortality for deliveries in this general-practitioner service is 23 5 per 1,000 total births, a figure that should be reduced by more careful selection of cases Hypertension, prematurity, breech presentation, multiple pregnancies and multiparity increased the perinatal mortality and, in the opinion of the writers, require hospitalization with specialist care Just under 20% of the deliveries were in this class The report emphasizes that there is greater scope for the use of local analgesia and the prophylactic use of ergonovine maleate in domiciliary obstetrics It also points out that it is a pity that the National Health Service does not do more to promote a full general-practitioner maternity service Unfortunately, owing to other commitments, the general practitioner cannot always be present at a confinement when called The survey shows that he attended 63% and was present at the actual delivery in only 48%, the local midwife or hospital physician delivered the remainder This is no reflection on the general practitioner but on his lack of facilities for good obstetric work The Royal College of Obstetricians and Gynecologists recognizes this and suggests that a way be found for him to devote sufficient time to maternity cases This might be attained by diminishing the number of other patients on his list and by making a commensurate increase in his fee for obstetric services

CORRESPONDENCE

HYPOGLYCEMIC VERSUS ANTIDIABETIC

To the Editor —The notes of caution in the editorial in the June 1 1957, issue of THE JOURNAL on the use of tolbutamide (Orinase) in the treatment of the diabetic are commendable I feel, however, that there are certain aspects of the subject which should receive more consideration

It seems to me that the problem of seeking oral substitutes for insulin has pointed up the important question of what it is we aim to accomplish in treating the diabetic The philosophical concepts which arose from the contributions of the early investigators in the field such as Rubner, Voit, Lusk, and Dubois would appear to indicate that this common and remarkable disease is primarily the result of a defect in the utilization of the dextrose molecule by the human organism What should, therefore, be the aim in therapy but to seek those measures which would correct this metabolic derangement and recreate the conditions necessary for increasing the consumption of dextrose by the body Certainly the discovery of insulin proved to be that boon to the diabetic in that it became possible for the diabetic to utilize amounts of glucose equal to normal amounts Surely the return of the blood sugar to limits close to the normal range served as a secondary accomplishment of the increased capacity for glucose utilization made possible by the use of insulin As a matter of fact, many physicians are sufficiently convinced that recreating an approximately normal capacity to utilize glucose is the basis for ideal therapy regardless of how the blood sugar is affected What most of us seem to forget is that the aim in therapy is not primarily to depress the blood sugar but to seek to re-establish a normal physiological state for carbohydrate utilization It seems to me that the whole idea of seeking an orally given agent with hypoglycemic properties is based upon a false concept, for one must realize that agents with this property need not necessarily have a salutary effect upon the derangement in carbohydrate metabolism which is so pronouncedly a *sine qua non* of diabetes mellitus

Some of us have lived through the era of synthalin and recognized its hypoglycemic properties to arise from specific organic damage to the liver It is well known that hepatectomy in the animal results in the quick onset of hypoglycemic convulsions, that ligating the hepatic artery frequently does the same thing that phosphorus and chloroform poisoning produce hypoglycemia, and that hepatitis and cirrhosis of the liver with cholemia are accompanied by hypoglycemia It seems to me that thus far the investigational studies with tolbutamide indicate that it is probably an hepatotoxic substance and interferes with the activity of glycogenolytic enzymes, thus producing its hypoglycemic properties Even if some of its activity is related to interfering with "insulinase," it still remains a liver poison I fear that the recent excitement about orally given hypoglycemic agents will ultimately meet the same fate as synthalin

CARBON TETRACHLORIDE SUBSTITUTES

To the Editor —Dr John H Schafer, in the Correspondence section (*J A M A* 163 1179 [March 30] 1957), rightly raised the question 'what substitutes" to the statement attributed to the New York City Poison Control Director, Harry Rabin, in an editorialized article in which he was quoted as saying that carbon tetrachloride is "so vicious that it should be banned from every home" There is no disagreement with Rabin s statement Fortunately, there are a number of commercial substitutes for carbon tetrachloride that are likewise noninflammable and in addition are considerably less toxic and hazardous for the home user The chief components of these substitute formulations are methyl chloroform, trichloroethylene, and perchloroethylene Although they are noninflammable and present far less risk of injury to the adult user, whose chief exposure is by inhalation, they should by all means possible be kept out of the reach of children, they cannot be taken internally without the possibility of serious effects Moreover, the substitute formulations commonly contain inhibitors of various sorts, which in turn possess varying degrees of toxicity Taken orally, methyl chloroform is reported to be somewhat more injurious than carbon tetrachloride, trichloroethylene and perchloroethylene are, however, considerably less poisonous by mouth than is carbon tetrachloride For the home user the price differential between carbon tetrachloride and its substitutes is insignificant These chlorinated hydrocarbons are recommended as replacement for carbon tetrachloride for spot-removing around the home But their careless use in unventilated spaces or in association with alcoholic intake before, during, or after use may still subject the user to possible injury

MISCELLANY

AMERICAN MEDICINE ABROAD—PUSAN, KOREA

Lou Hazam

This is the first of a series of on-the-scene reports from the 'March of Medicine' production team, which is traveling around the world to film an hour-long television program on the work of American doctors abroad—the services they perform, the conditions they face, the personal satisfaction they receive in their unofficial roles as America's medical diplomats The author, Mr Lou Hazam, has written all but one of the 'March of Medicine' scripts since the series started in 1952 In this article, he tells of the dedicated work of the Maryknoll Sisters in Pusan, Korea Also on the 'March of Medicine' itinerary are such places as Hong Kong, Sarawak, Burma, Nepal, India, Ethiopia, Lebanon, Turkey, and Guatemala The program, sponsored and produced by Smith, Kline & French Laboratories in cooperation with the American Medical Association, will be seen in color next spring over the NBC television network —Ed

High on a hill overlooking the sprawling, bursting-at-the-seams city of Pusan, Korea—swelled by thousands of refugees from the Communist north—four American doctors, who wear a special and distinctive habit, examine and treat the sick who line up outside their door by the hundreds, often as early as midnight They are the Maryknoll Sisters of St Dominic

"They just bed down and wait for us," said Sister Angelica, the Superior, and a nurse by training, showing me the long line that stretched out of sight down a cobblestoned alley to the street "I've gradually persuaded them not to start a line at 2 a m , but as it is, they're there when we get up—there before dawn "

I looked down the line, and as far as the eye could see were the sick, the halt, the lame, the blind, little wrinkled old women sprawled on faded, tattered pieces of canvas infants wrapped on their mothers backs balloon-trousered men, their families clustered close around them dark-haired children, wearing nothing much from the waist down scores squatting in pain, rocking back and forth as they waited

"They come from as far away as Seoul,' I heard the Sister's voice go on "But by far, most of our patients come from the homes, the huts, the shanties, and tents around Pusan And since some have no homes, they come to us right off the streets Sometimes they come on foot, and many times you see them being carried in on the back of some member of their family "

She told me that often they come too late, after precious weeks of trying to treat the sickness themselves—perhaps by burning the skin over the afflicted area with a hot punk

"You know the idea If you can create a pain worse than the one that hurts you, you somehow make the first pain better Or the old pagan idea—fire cleanses everything "

The history of the Maryknolls in Korea goes back to 1924, when the order was first established in the north There they remained until World War II started Korea was, of course, Japanese dominated at the time, and the Sisters were sent back to the States on the Gripsholm with the first exchange of prisoners They returned in 1949 to Pusan, only to be caught by the Communist invasion from North Korea This time they were evacuated to Japan, where they remained until April, 1951 Finally, with General MacArthur's express permission, they were allowed to return—the first civilian medical team to go back to Korea The armed forces gave them a former Japanese estate totaling some four acres, all walled or fenced in When I found them, they were working along just as if nothing had happened to interrupt them

"We open the gate at 8 30 in the morning,' continued Sister Angelica "We send out one of our nurses first, to go along the line and seek out the critically ill We try to take care of them ahead of the others "

I watched the gates open and the nurse emerge and proceed up the line I saw the patients gather about her listened to families recite the history of their troubles in Korean, which I was sorry I could not understand Once, satisfied, I saw her motion a woman, propped against the fence, inside Quickly her husband bent down, pulled her somehow on his back and then trotted his burden through the gates—two doll-like figures whom I was told had walked miles to reach here the night before

What kind of cases do these Sisters see? They showed me a chart

Diagnosis	*Frequency*
Cardiac	5–10% of all patients
Cirrhosis of the liver	4% of all patients
Diabetes	2% of all patients
Hypertension	5% of all patients
Malnutrition	90% of all patients
Tuberculosis	1,700 average per month

Yes, mostly tuberculosis—whatever else may bring them in—and malnutrition underlying almost all illness

The Sister doctors examine and treat patients in the clinic from morning until about 5 30 in the afternoon, assisted by a few Korean doctors and nurses on the staff, and augmented by Sisters trained as pharmacists and laboratory technicians The doctors, considering the unending stream of patients day after day, appeared remarkably cheerful Sister Agnus Therese and Sister Lois had both graduated from Marquette University Medical School and interned at St Vincent's Hospital in New York Sister Gilmary secured her medical degree from the Women's Medical College, Philadelphia, and studied pediatrics at Duke University Hospital Sister Maria Fidelis had also attended Marquette and had gone on to further work in Cincinnati They are assisted by 9 or 10 registered nurses, all from the States

Sometimes there have been more than a thousand patients waiting in line to see them The record over the years

Year	No of Patients
1951	180 697
1952	410,529
1954	488 991
1955	381 742

The operation is strictly an outpatient clinic operation While they are presently building a hospital, they have no beds available Patients are treated, go home and return when necessary, lining up at one side of the gate as returning patients As pointed out, a high percentage is afflicted with tuberculosis—pulmonary the highest—tuberculosis of the bone, and also meningitis, especially in children, and many with peritonitis

Second on their list were intestinal infections of various kinds, particularly those that produce the typhoids Korea is called a 'parasitologist's paradise because of the number and variety of parasites found in that country For example, roundworm, hookworm, ameba, lung and liver flukes, and Trichuris As one medical observer put it, "multiple parasitic infections occur frequently, the coexistence of two being more common than a single infection' Ninety-five per cent of the Koreans are believed to have parasitic infection

According to those who have studied the problem, the main source of ill health has been established as (1) poor sanitation, (2) the eating of raw fish, and (3) the traditional use of night soil as fertilizer—all this plus the impact of war, bringing with it food shortages and inadequate housing

Sister Gilmary is in charge of the clinic s tuberculosis program and leaves the clinic grounds every afternoon to go on a home visit

'This new program of ours grew out of the conviction that we were doing more harm than good treating recognized adult tuberculosis patients here at the clinic, where those with positive sputums could be a menace to other patients Also, we knew that in order to be treated properly, they should be resting, and not have to walk to the clinic So we restricted our tuberculosis program to those who reside in our own area, where we could readily reach them, and put them to bed at home A nurse sees each patient every week, and I try to see each one at least once a month We never make these visits at any specified time, she declared, 'since we want to see if the patient is really cooperating "

The 'March of Medicine' will include such a visit in its film report of the Maryknoll Clinic

As I was leaving, a little boy about 5—just back from school—ran up and hugged Sister Angelica s skirts

'And who's this?' I asked

'Oh, this is our Ashcan baby, Bundo That's Korean for Benedict

"Ashcan baby?'

"Yes He was dropped in an ashcan at our gate when he was just a year and a half old that's a guess—the age, I mean We found him and brought him in and warmed him by the fire He was just skin and bones After a time we found a Korean family on the grounds to look after him We support him, of course—providing the clothing he needs and food, and pay the family for caring for him "

She smiled apologetically as she held him close to her "Just a little extracurricular activity," she said

I looked at the fat, healthy, laughing little Bundo, and around me at the busy sisters, serving so far from home in the best tradition of medicine, bade them good-bye and turned my face toward Hong Kong—next stop on the March of Medicine's' agenda—wondering what I'd done with *my* life

MEDICOLEGAL ABSTRACTS

Statute of Limitations Concealment of Cause of Action—This was an action for damage for injuries allegedly caused by the malpractice of the defendant physician The jury returned a verdict in favor of the plaintiff and the trial court sustained the defendant's motion to set aside the verdict and grant the defendant a new trial From this action of the trial court, the plaintiff appealed to the Supreme Court of Appeals of West Virginia

The defendant removed the plaintiff's gallbladder on June 16, 1947 During the time she was in the hospital following the operation, and in the course of office calls after she was discharged from the hospital, the plaintiff complained to the defendant of pains in her abdomen The defendant assured her, however, that she could not expect to recover immediately from an operation such as she had had and that she would be all right From August, 1947, to October, 1953, the plaintiff consulted a number of physicians for various ailments She complained to them of pain in her abdomen, they gave her answers similar to that of the defendant Finally in October, 1953, the physician who was then treating the plaintiff had x-rays taken and they disclosed a hemostat in the plaintiff's abdomen Suit was filed in 1954

The defendant contended that the plaintiff's action was barred by the one-year statute of limitations with respect to malpractice Section 55-2-17 of the West Virginia code provides that the statute of limitations will be tolled if the person, against whom the right of action has accrued, obstructs the prosecution of such right by any indirect ways or means In order for this provision to apply, said the supreme court, there must be an affirmative act designed to conceal the existence of liability, and to operate in some way upon the plaintiff so as to prevent or delay suit, mere silence is not sufficient The evidence showed that the defendant physician had no knowledge of the presence of the hemostat in the plaintiff s abdomen until after the taking of the x-rays in 1953 Since the cause of action against the defendant accrued at the time of the gallbladder operation and there was no actual knowledge, fraud, or concealment on the part of the defendant which would toll the statute of limitations, the supreme court concluded that the judgment of the lower court in favor of the defendant physician should be affirmed *Gray v Wright, 96 S E (2d) 671 (W Va, 1957)*

INTERNAL MEDICINE

Sporadic or Non endemic Familial Cretinism with Goiter J B Stanbury and E M McGirr Am J Med 22 712-723 (May) 1957 [New York]

The authors describe 3 types of familial nonendemic cretinism with goiter resulting from primary failure at any of the essential steps in the synthesis of the thyroid hormone In the first type, which occurred in a 16-year-old girl, the defect was a failure to utilize trapped iodide The patient was 1 of 7 siblings, 4 of whom, including the patient, were cretins with goiter She was dwarfed, grossly retarded mentally, and had a large nodular goiter, over which a bruit and a thrill were present The concentration of the protein-bound iodine in the serum was 1 mcg per 100 cc When radioactive iodine (I^{131}) was given orally, a large fraction of it accumulated with remarkable rapidity in the thyroid Maximal values were observed in the gland within 2 hours When the accumulation had reached a plateau the patient was given a dose of 2 Gm of potassium thiocyanate Immediately there was a striking and rapid disappearance of the I^{131} from the gland Thyroidectomy was performed, and only minute amounts of iodine were detected chemically in the thyroid Similar observations were made in 2 goitrous and cretinous brothers of the patient The metabolism of iodine appeared to be identical with that in patients receiving full doses of the antithyroid drugs of the thiocarbamide group Since these drugs exert their antithyroid effect by inhibiting the transfer of iodide to tyrosyl residues through an enzymatically controlled oxidative step, it seems reasonable to suppose that the capacity to perform the oxidative step was lacking in these patients While the thyroid was able to concentrate trapped iodide from the serum it could not produce iodotyrosines from tyrosyl residues and iodide, presumably because of lack of an oxidative enzyme

In the second type, present in a 25-year-old woman who was physically stunted with disproportionately short extremities, mentally backward, and with a multinodular goiter, the rate of disappearance of stable iodine from the thyroid was calculated from measurements of the rate of disappearance of I^{131} from the gland and the urinary content of I^{131} and stable iodine before and during the administration of 1-methyl-2-mercaptoimidazole (Methimazole), a drug which blocks the incorporation of iodide into organic compounds The rate of disappearance of iodine proved to be greater than could have been possible if the secretion product had been exclusively triiodothyronine or thyroxine, else the patient would have been thyrotoxic Also, when the amount of "hormone" leaving the gland was calculated from mean values for urinary excretion of stable iodine and uptake of I^{131}, it was found that more than 1 mg of iodine (5 times the normal value) was secreted daily Chromatographic study of the serum disclosed normal amounts of triiodothyronine and thyroxine in the blood, but 4 days after a large dose of I^{131} only a trace of thyroxine could be identified in the thyroid Iodine in the gland was almost entirely present as monoiodotyrosine and diiodotyrosine These observations suggest that in this second type the thyroid gland cannot couple iodotyrosines into iodothyronines with sufficient speed to secure an adequate supply of hormone The presumption is that this defect is due to failure of enzymatic coupling, but proof is lacking

The third type of sporadic familial cretinism occurred in a 27-year-old man with multinodular goiter Calculation of the rate of disappearance of I^{131} from the thyroid, chromatographic analyses of the patient's serum at various times after administration of I^{131}, analysis of the thyroid after thyroidectomy, and a detailed chromatographic study of urine specimens suggested that the cretinism resulted from failure of iodotyrosines to deiodinate The hormone precursors monoiodotyrosine and diiodotyrosine escape from the thyroid gland into the blood and then into the urine because of lack of the enzyme, deshalogenase The result is a leak of iodotyrosines of sufficient magnitude to cause serious iodine deficiency Other biochemical abnormalities which have not yet been fully elucidated have been described by other workers Genetic studies support the concept of the hereditary transmission of some type of sporadic cretinism with goiter The condition shows a high familial incidence, and consanguineous matings are strikingly frequent among the parents of cretins The combined results of biochemical and genetic studies made in Scottish and in additional similar Dutch cases suggest that a single recessive gene controls the presence or absence of a single deiodinating enzyme

To What Extent Is Asthma an Allergic Response to House Dust? R Genevrier, L Michelet and M Claude Semaine hôp Paris 33 1546 1549 (April 20) 1957 (In French) [Paris]

Skin tests were made in 244 patients referred to the authors in 1955 for investigation of supposed respiratory allergy These patients, excluding 29 who had hay fever, fell into 3 groups (1) 14 with spasmodic coryza, (2) 23 with spasmodic cough and bronchial syndromes,

The place of publication of the periodicals appears in brackets preceding each abstract

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals Requests for periodicals should be addressed Library, American Medical Association Periodical files cover 1948 to date only and no photoduplication services are available No charge is made to members but the fee for others is 15 cents in stamps for each item Only three periodicals may be borrowed at one time, and they must not be kept longer than five days Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them and (3) 178 with asthma, with which this study is primarily concerned Positive skin reactions were obtained in 4 (28%) of the first group, 1 (4%) of the second group, and 113 (63%) of the third group Sensitivity to house dust was present in 108 of the patients with asthma, to feathers in 80, and to cotton in 25 Sensitivity to other allergens was much more rare, the commonest, to wool, being found in only 8 patients Many of the patients had a threefold sensitivity to house dust, feathers, and cotton The discovery of 67% of positive skin reactions in 178 patients with asthma is significant in itself, but it becomes more so when the findings are considered in relation to the age of the patients Sensitivities were present in 92% of those aged from 20 to 40 years The fact that a lower percentage was found in the patients under 20 was probably due to a greater importance of food allergies in the young Allergies of this kind were excluded from this study The percentage of positive reactions declined substantially in patients over 40, the decline being the greater the older the patient and the more recent the asthma Asthma in persons under 40 thus seems to be essentially the manifestation of an allergy and, except in young children in whom food allergies are undoubtedly important, this allergy is essentially respiratory in origin Nonallergic factors, such as bronchial infection, endocrine disorders, neuropsychiatric manifestations, and metabolic disturbances, on the other hand play a larger part in the dyspneic symptoms of older asthmatic patients

The allergenic importance of house dust has long been recognized, but the exact nature of the specific antigen it contains is not known Clinical observations have shown that many patients with asthma who are sensitive to house dust have no sensitivity to any of its known constituents Many attempts have been made to determine the chemical composition of the antigenic substance, but none has succeeded Indications are, however, that it is composed of a nitrogenous substance with large molecules, associated with hydrocarbons The excellent results obtained in asthmatic patients by desensitizing them to house dust provide further proof of the part played by house dust sensitivity in the production of asthma

Newborn Pneumonitis Virus (Type Sendai) Evidence of Infection in South-West Scotland R G Sommerville Brit M J 1 1145-1148 (May 18) 1957 [London]

Complement-fixation tests were performed on paired serums obtained from 175 adults with pneumonia, 97 infants with pneumonia, and 172 patients with influenza in south-west Scotland Newborn pneumonitis virus (type Sendai), which was isolated first from the lungs of newborn infants who died during an outbreak of pneumonitis in Japan, was used as antigen For comparison, hemagglutination-inhibition tests for antibody reacting with newborn pneumonitis virus were performed on 381 of these paired serums obtained from 162 adults with pneumonia, 58 infants with pneumonia, and 161 patients with influenza Evidence was found in adults for the existence of an agent which is capable of producing this antibody A fourfold rising titer was detected by complement-fixation tests in the serums of 9 patients, and clinical details recorded from these patients revealed that the infection presented as pneumonia in 3 and as mild influenza-like illness in 6

Pleuropulmonary Symptoms of Acute Leukemia E S Mazzei and G Masnatta Prensa med argent 44 1-5 (Jan 4) 1957 (In Spanish) [Buenos Aires]

The authors observed 4 patients with acute leukemia Review of the literature showed that the initial respiratory symptoms of acute leukemia are apparently infrequent On the basis of their observations and of 12 reports, which analyze the respiratory manifestations of acute leukemia, the authors arrive at the following conclusions The frequency of the anatomic lesions is greater than the clinical and radiologic findings This became evident on the miscroscopic studies of the anatomic lesions Pathogenetically, respiratory symptoms are caused either by infiltration of the parenchyma, which begins in the alveolar septum, by bronchial or bronchiole compression, or by subpleural infiltration There is a contiguous infiltration into the blood vessels, which causes pulmonary infarction According to clinical and radiologic findings, symptoms may start with respiratory manifestations similar to those caused by other pulmonary diseases (such as tuberculosis, neoplasm, acute inflammatory pneumopathy, pleurisy) The complete hematological examination can establish the cause

Inflation of Esophageal Hernial Sac in the Course of Induced Pneumoperitoneum J M Workman Am Rev Tuberc 75 823-827 (May) 1957 [New York]

The author reports the occurrence of esophageal hiatal hernia detected by roentgenographic studies as a result of inflation of the hernial sac in the course of pneumoperitoneum which was induced in a 66 year-old woman with pulmonary tuberculosis Detailed barium studies showed that the fundal portion of the stomach herniated through the esophageal hiatus The esophagus was short and tortuous, with some dilatation Air from the pneumoperitoneum extended above the diaphragm and in the hernial sac This complication of pneumoperitoneum appears to be extremely rare, only one other case, in a 45-year-old patient with findings very similar to those described, has been reported Formation of a redundant herniated peritoneal sac is one of the basic structural defects in sliding hiatal hernia Since this form of diaphragmatic hernia is not at all uncommon, the rarity of this complication of pneumoperitoneum is surprising

It may be that in most cases of sliding hiatal hernia the redundant peritoneal sac is considerably smaller than it was in this patient and in the case collected from the literature and for that reason might not be easily identifiable on roentgenographic or fluoroscopic examination The muscular tone of the collar' of the diaphragmatic hiatus may be adequate in young patients with hiatal hernia to prevent ingression of air into the sac Both patients in whom induced pneumoperitoneum was complicated by esophageal hiatal hernia were in the older age groups Pneumoperitoneum is less often given to patients over 40 years of age because it is less often effective The appearance of this complication is an indication for discontinuing the pneumoperitoneum

Evidence of Psychosocial Factors in the Development of Pulmonary Tuberculosis N G Hawkins, R Davies and T H Holmes Am Rev Tuberc 75 768-780 (May) 1957 [New York]

In an attempt to test the hypothesis that a life organizational stress situation of significant proportion appears typically shortly before the onset of pulmonary tuberculosis a group of 20 sanitorium employees 17 male and 3 female, who became ill with tuberculosis was compared with an individually matched group of 20 employees who remained well Each of the groups contained 1 physician, 4 registered nurses and 12 subordinate nursing and auxiliary personnel The matching included age, race, sex, marital status, education, time of employment job classification, income, skin test reading, appearance of roentgenograms of the chest, and previous record of certain chronic conditions Those who became ill had experienced a concentration of difficulties such as domestic strife, residential and occupational changes, and personal crises in the course of the 2 years preceding the change in a series of roentgenograms of the chest taken at 3-month intervals and leading to determination of pulmonary tuberculosis This concentration of difficulties, or situational crisis, was significant in comparison with the experience of the group of employees who were well The tuberculous group also evidenced a significant degree of psychoneurotic pathology and did not recognize or could not admit their personality deficit on questions in which this recognition was obvious

The conclusion appears reasonable that many of the employees who became ill did so in a situation of stress which would be conducive to a lowered resistance It is not suggested that stress must invariably accompany infection in order to produce progressive tuberculosis in man or that stress, if present, must be psychic in nature Within the acknowledged limitations of the test, however, the postulation of psychosocial crisis as one of the precipitant causes is tenable

The Effect of Butyl Sulfanilylurea on the Blood Lipids in Diabetes Mellitus G Corsini and L Guacci Minerva med 48 1119-1124 (April 4) 1957 (In Italian) [Turin, Italy]

Twenty-two diabetic patients, 14 female and 8 male, 21 to 78 years of age, were treated with butyl sulfanilylurea for a period of 22 days A dose of 2 5 to 3 Gm per day was administered for the first 2 or 3 days The dose was reduced to 2 Gm per day for the following 8 to 10 days and to 1 Gm per day for the remaining 10 to 12 days Ten patients had a mild form of diabetes, 8 a moderate form, and 4 (3 of whom were under 35 years of age) a severe form The patients were divided in 3 groups of 10, 7, and 5 patients respectively Insulin therapy was discontinued for at least one week in the patients of the first and second group and was continued but with smaller doses in patients of the third group The glycemia became normal and glycosuria disappeared after administration of the drug in the 10 patients of the first group, 7 with mild diabetes and 3 with moderate diabetes The drug reduced but did not bring to normal the glycemia and glycosuria in the 7 patients of the second group, of which 3 had mild diabetes, 3 moderate diabetes, and 1 severe diabetes The drug had no effect on the 5 patients of the 3rd group, which consisted of 2 patients with moderate diabetes and 3 with severe diabetes The value of total lipemia of the patients of the first group was reduced from an average of 741 mg per 100 cc before treatment to 610 mg (16 mg per 100 cc more than normal) after treatment, glycerides from 178 to 124 mg per 100 cc (38 mg per 100 cc more than normal), phosphatides from 261 to 225 mg per 100 cc (12 mg per 100 cc more than normal), and steroids from 264 to 223 mg per 100 cc (39 mg per 100 cc more than normal) The value of total lipemia of the patients of the second group was reduced from an average of 778 mg per 100 cc before treatment to an average of 681 mg after treatment (29 mg per 100 cc more than normal), glycerides from 216 to 161 mg per 100 cc (79 mg per 100 cc more than normal), phosphatides from 253 to 229 mg per 100 cc (14 mg per 100 cc more than normal), and steroids from 263 to 243 mg per 100 cc (51 mg per 100 cc more than normal) The value of the total lipemia of the patients of the third group increased from an average of 739 mg per 100 cc before treatment to an average of 825 mg (56 mg per 100 cc more than normal) after treatment, glycerides from 175 to 228 mg per 100 cc (163 mg per 100 cc more than normal), and phosphatides from 280 to 313 mg per 100 cc The concentration of steroids was not affected by the treatment

SURGERY

Mitral Commissurotomy and Late Postoperative Rheumatic Manifestations A Actis-Dato and S Olivero Minerva med 48 1411-1416 (April 21) 1957 [Turin, Italy]

The frequency of immediate and late postoperative complications due to a recurrence of rheumatic manifestations was studied in 200 patients, 49 male and 151 female, who had been subjected to mitral commissurotomy The patients were 20 to 51 years of age, most of them between 20 and 25 They were followed up for a period of 2 to 5 years Rheumatic or rheumatic-like manifestations were not observed in 43 patients before the operation Seventy-two of 91 patients with typical rheumatic infection were under 25 years of age Pleural adhesions were found in 15 patients during the operation 7 of these patients had presented rheumatic manifestations before the operation Adhesive or constrictive pericarditis was found in 4 patients Some accumulation of fluid in the pleura was found in 8 patients Aschoff's nodes were present in 8 of a group of 30 patients in whom a histological study of the auricles was made Twenty-two patients had rheumatic relapses within 50 days after the operation Relapses occurred in some a few months after the operation Fourteen of the 22 patients had articular rheumatism shortly before the operation, and 4 presented frequent tonsillitis Rheumatic manifestations had not been observed before the operation in 2 patients Late rheumatic relapses were observed in 57 patients, only 47 of whom presented rheumatic infection before the operation The authors think that there is a close relationship between the existence of rheumatic infection before the operation and the occurrence of postoperative rheumatic relapses Relapses were most frequent among patients 20 to 25 years of age

A Five to Ten Year Survey of Pulmonary Resection for Tuberculosis R F Lane and W E Harrison Canad M A J 76 845-846 (May 15) 1957 [Toronto, Canada]

The results of a survey 5 to 10 years after operation on the first 100 patients subjected to pulmonary resection for tuberculosis at the Willow Chest Center in Vancouver B C are reported There were 18 surgical and postoperative deaths Of the 82 survivors, 25 had undergone pneumonectomy and 57 lobectomy The sputum was free from tubercle bacilli in 77 of the 82 patients Sixty-eight of the survivors have full-time and 8 have part-time employment Of the 43 women in the group, 14 have had 27 pregnancies with 20 live births, without any activation of the tuberculous process There were 2 spontaneous abortions, and in 4 women abortion was induced

Supraclavicular Exploratory Excision of Lymph Nodes of Superior Thoracic Aperture to Ascertain Operability of Bronchial Carcinoma V H Denk and P Wurnig Thoraxchirurgie 4 504-508 (April) 1957 (In German) [Stuttgart, Germany]

The authors found that 41% of the patients subjected to thoracotomy because of bronchial carcinoma were inoperable, despite the use of all available clinical methods Since palliative resection does not improve the life expectancy, they believe that operability should be ascertained before the operation Reports of some observers indicated that metastatic involvement of the supraclavicular lymph nodes could be expected in 10% of the patients with clinically operable bronchial carcinoma To verify this, the authors performed bilateral exploratory excision of the cervical lymph nodes of the superior thoracic aperture in 100 patients with clinically operable bronchial carcinoma, that is, in those who had no palpable enlargement of the supraclavicular lymph nodes The 100 patients included 21 with squamous-cell carcinoma, 43 with polymorphic carcinoma, 18 with small-cell carcinoma, 1 with adenocarcinoma, 1 with endothelioma, and 16 with unidentified carcinoma, because operation of the clinically identified bronchial carcinoma was contraindicated by internistic factors

Cancerous involvement of the supraclavicular lymph nodes was found in 5 of the 100 patients in 1 with polymorphic carcinoma and with atelectasis of the upper lobe on the left side, in 1 with squamous-cell carcinoma with incomplete atelectasis of the upper lobe on the right side, and in 3 patients in whom enlargement of the hilar lymph nodes could be seen on the tomogram Two of these last 3 patients had a small-cell carcinoma and the third an adenocarcinoma The authors believe that bilateral exploratory excision of the cervical lymph nodes should be done in patients with centrally located bronchial carcinoma in whom the process is no longer limited to one segment Exploratory excision should always be carried out in patients with carcinoma of the branch bronchus and of the stem bronchus in which enlarged hilar lymph nodes can be recognized, insofar as there are no other signs of inoperability It is doubtful if exploratory excision is of much help in patients with carcinoma of the apical segment of the upper lobe, because in these patients inoperability is more often indicated by the tumor itself or by metastases in the upper mediastinum In patients with peripherally located carcinoma, exploratory excision is indicated only if the roentgenogram shows enlarged hilar lymph nodes However, bilateral exploratory excision of the supraclavicular cervical lymph nodes should always precede thoracotomy if the stage of development of the carcinoma cannot be definitely ascertained from the roentgenogram

Bilateral Adrenalectomy for Advanced Carcinoma of the Breast M Katz and H C Saltzstein Am Surgeon 23 301-307 (March) 1957 [Baltimore]

Bilateral adrenalectomy and oophorectomy was performed on 389 patients with advanced cancer of the breast Of these, 379 were collected from various sources in the literature and 10 of the authors' own patients were included For 23 patients it was too early for evaluation There were 29 (7 9%) post-operative deaths, 159 (43 4%) were unaffected by adrenalectomy, and 178 (48 7%) showed moderate to marked improvement Death occurred within 30 days after operation Subjective improvement was remarkable in patients with bone lesions and local recurrences They responded better to adrenalectomy than patients with visceral metastases, bone pain showed a dramatic disappearance as early as 24 hours after the operation The bedridden patients became ambulatory while the objective signs remained Disappearance of respiratory symptoms occurred without change in the roentgenologic picture The average period of remission is 9 to 10 months for those who respond to adrenalectomy, although 10 to 15% had a remission for 2 years and more Postmenopausal women had a slightly better response than premenopausal women They should be treated by combined oophorectomy and adrenalectomy, since the ovaries continue to secrete estrogens that can sustain the growth of the breast cancer

The Management of Bleeding Peptic Ulcer J B Holloway, J S Robinson and J B Thoroughman Am Surgeon 23 195-204 (March) 1957 [Baltimore]

The methods of treatment of 519 out of 1,998 patients with bleeding peptic ulcer admitted to hospital during the period from 1946 to 1955 were outlined There were 132 patients who did not require surgical treatment, 314 had had sufficient hemorrhage to cause some hematological changes No operation was performed on 221 patients, 12 of these refused surgical treatment and 6 had complications which precluded any elective surgical procedure All patients ceased bleeding promptly on a medical regimen High subtotal gastrectomy was performed in 46 patients, gastroenterostomy with vagotomy in 9, and hemigastrectomy with vagotomy in 38 Death occurred in one patient, caused by homologous serum jaundice 6 weeks after the operation Immediate surgical intervention offered the only hope of preventing death in 73 patients None of the 9 patients who did not undergo surgery survived Of the 64 patients who underwent surgery, 8 died High subtotal gastrectomy was performed on 26 hemigastrectomy with vagotomy on 36, and ligation of the bleeding artery on 2 Postoperative complications occurred in 43 of these patients Massively bleeding peptic ulcer is most effectively managed by a medicosurgical team Surgical treatment, if elected, should be performed without delay Blood and fluid should be administered generously preoperatively but rather conservatively after operation Diagnosis should be confirmed by roentgenographic examination, if possible, otherwise by surgical exploration The ulcer should be removed or exteriorized at the time of surgery Blind gastrectomy may be indicated in certain cases Hemigastrectomy with vagotomy was the surgical procedure that offered the best immediate and long-term results

Colotomy, Coloscopy, and Colectomy in the Management of Polyps of the Large Intestine S McLanahan and R E Martin Ann Surg 145 689 698 (May) 1957 [Philadelphia]

The authors report on 3 women between the ages of 37 and 50 years with polyps of the colon A pedunculated polyp at the level of the junction of the descending colon and sigmoid was revealed by an air-contrast study and confirmed by colotomy in the first patient, a transfixion suture was placed at the base and the polyp excised Two and a half years later the patient was symptom-free and well Sigmoidoscopy revealed a large polyp with a moderately broad base, 15 cm above the anal margin, in the second patient On laparotomy the polyp could be moved within the colon over a range of approximately 7 5 cm Because of its size and the sessile nature of the base, resection was carried out, with removal of a segment approximately 12 7 cm in length with the adjacent mesentery Coloscopy was done by passing a proctoscope proximally for 12 cm No other polyps were seen End-to-end anastomosis was accomplished and the abdomen closed The patient has been followed up for 1 year after the operation and has remained well In the third patient, with a 3-year history of blood and mucus in the stools, a deformity in the rectosigmoid areas was revealed by roentgenographic examination and interpreted as caused by diverticulitis Because of the suspicion that the diverticulitis was masking carcinomatous lesions, a partial left colectomy was performed It revealed many polyps of varying sizes associated with diverticulosis and diverticulitis Further resection was carried out to the midtransverse colon, and again the intestine contained scattered polyps The remaining proximal portion of the colon was then removed, and a few additional polyps were found The ileum was anastomosed end-to-end with the upper part of the rectum Pathological examination of the operative specimen revealed multiple papillomas showing early carcinomatous changes in one large pedunculated papilloma Sigmoidoscopy was performed 5 years after the operation and did not reveal any polyps

Three matters are of special interest with regard to polypoid disease of the colon (1) the close relationship which adenomatous polyps and papillary tumors bear to carcinoma, (2) the more frequent occurrence of multiple polyps than has been generally appreciated, (3) the indications that cancer of the large intestine and rectum is among the most frequently occurring cancers in man For the uncomplicated pedunculated adenomatous polyp, colotomy and polypectomy is usually adequate treatment, though exceptions exist and there is a growing tendency to carry out segmental resection more often The solitary sessile polyp usually is best managed by segmental resection The surgeon is under obligation to determine the presence or absence of other polyps In addition to palpation, transillumination, and direct examination of the exposed lumen, coloscopy is an available and helpful method Despite certain disadvantages, more frequent employment of this maneuver is encouraged The trend in treatment of multiple polyps in the colon is toward a more radical approach in order to effect better cancer prophylaxis Abdominal colectomy and ileoproctostomy may often be the procedure of choice Evidence is available to indicate that satisfactory function of intestine can be expected Surgical judgment is needed in the selection of patients for this radical approach

Ligation of the Inferior Vena Cava in Decompensated Mitral Heart Lesions E N Meshalkin and B E Imnaishvili Khirurgiya 33 36-45 (No 4) 1957 (In Russian with English summary) [Moscow]

The authors report their experience with ligation of the inferior vena cava in patients with mitral insufficiency in whom radical surgical interventions were contraindicated because of grave conditions caused by decompensation Ligation of the inferior vena cava was performed in 70 patients, but 20 of these patients died In order to reduce the risk involved and to be better able to judge the indications and contraindications to this operation, a preparatory physiological test was carried out Cuffs that interrupted the venous return for varying periods of time were applied to both thighs The venous stasis was gradually increased to 2 hours in the course of 1 week It was found that ligation is contraindicated in patients in whom the condition becomes worse when the cuffs are applied, in that there is a decrease in arterial pressure, an increase in dyspnea, and the cardiohemodynamics show deterioration

The patients were operated on under local anesthesia by an extra-abdominal approach with the patient lying on his left side Eleven of the 20 deaths occurred in patients who were in the late stages of the disease, that is, when decompensation had become irreversible In 15 patients in whom ligation of the inferior vena cava was carried out because their condition was too grave to permit a commissurotomy, this operation was performed from 3 to 8 months after the ligation, with death resulting in 3 of them The authors regard ligation of the inferior vena cava as a palliative measure for those patients in whom the radical operation (commissurotomy) is contraindicated It benefits these patients because it improves the circulation

Determination of the Portal Pressure by Puncture of the Spleen E I Halperin Khirurgiya 33 109-114 (No 4) 1957 (In Russian with English summary) [Moscow]

The determination of the portal pressure has become important since surgical methods have been developed for the treatment of cirrhosis of the liver It is an aid in establishing the diagnosis, and it indicates the advisability of surgical treatment The fact that the red pulp of the spleen is connected with the veins of the portal system in the spleen suggested that measurement of the pressure in the spleen must also show the correct value of the portal pressure To verify this, tests were made on 22 dogs and 6 rabbits The pressure in the portal vein was taken simultaneously The pressure in the spleen ranged from 100 to 220 mm H_2O and the portal pressure from 102 to 220 mm H_2O, that is, they were practically identical Later this method of measuring the portal pressure by puncture of the spleen was tried in 9 patients with cirrhosis of the liver The method caused no complications, either in the patients or in the laboratory animals

NEUROLOGY & PSYCHIATRY

Spread of Poliovirus Infection During an Epidemic of Unusual Severity Woodbury County, Iowa, and Dakota County, Nebraska, 1952 P F Wehrle, W McD Hammon, L L Cornell and R M McAllister Am J Hyg 65 386-403 (May) 1957 [Baltimore]

Studies of the evaluation of Red Cross gamma globulin in the prophylaxis of poliomyelitis afforded an opportunity for detailed study of the epidemiology of the disease For that study areas were selected on the basis of an unusually high incidence of poliomyelitis with a relatively high proportion of paralytic involvement Since these studies afforded an unusual opportunity for careful and detailed follow-up by a single group of investigators over a relatively long period of time, the epidemiologic findings are believed to be of value They are presented here for Woodbury County, Iowa, including Sioux City, and for Dakota County, Nebraska, including South Sioux City The principal industry for the two-county rural area is general farming, while the chief industries of the urban area are manufacturing and meat processing A review of the water supply, sewage disposal and general sanitation of the area did not disclose factors of likely significance in the epidemiology of poliomyelitis An outbreak of type 1 poliomyelitis of unusual intensity that occurred in this 2-county area in 1952 is described Unusual features noted were extremely high age-specific and total infection rates and unusually high paralytic and bulbar rates This outbreak followed 6 years of unusually high poliomyelitis incidence in this same area Yet even following this 7-year period, serologic evidence indicated that many susceptible children remained in this area The follow-up study differed somewhat depending upon the age group of the patient and the date of onset of the illness All patients in the 1-to-11-year age group were seen by members of the study team Those with onset prior to the date of the injection clinics (July 21 to July 26) were seen as time permitted later during the course of the epidemic and a detailed muscle evaluation was done Patients outside the 1-to-11-year age group were seen as time permitted The hospital records were reviewed Gamma globulin did not appear to prevent inapparent infection with poliomyelitis virus, since age trends during the latter portion of the epidemic were similar to those during the earlier course of the outbreak Epidemiologic evidence is presented which suggests that the opening of schools during the epidemic period did not change the course or age trends of the outbreak Epidemiologic and serologic evidence presented suggests that the poliomyelitis virus active in this area during 1952 was one with unusual pathogenic properties, probably leading to clinically recognized disease in about 5 per 100 susceptible children infected

Studies on the Development of Natural Immunity to Poliomyelitis in Louisiana II Description and Analysis of Episodes of Infection Observed in Study Group Households H M Gelfand, D R LeBlanc, J P Fox and D P Conwell Am J Hyg 65 367-385 (May) 1957 [Baltimore]

This is the second of 2 reports, in the first of which a plan for studying the circumstances relating to the natural acquisition of specific immunity to poliomyelitis was presented This plan, basically, provided for the observation during the early years of life of about 150 newborn infants (index children) in as many households selected to be representative with respect to residence in one of 3 study areas (New Orleans, Baton Rouge, and the Evangeline area), family size, race, and socioeconomic status Information concerning the entire household, as well as blood and stool specimens from the index children, were collected monthly as a routine Serums were obtained from all household members on admission to the study and annually thereafter As infection of the index child was detected, families were revisited to obtain both added information and specimens (blood and stool) from all household and indicated extrahousehold contacts Standard tissue-culture methods were employed both for detection of neutralizing antibodies in serums and for isolation of polioviruses from stools All statements as to virus isolation are based ultimately upon the use of cultures containing primary growth of monkey kidney cells since, although HeLa cell cultures were used exclusively initially, all specimens failing to yield virus in this system were retested in kidney cell cultures

This second report presents data relating to 114 documented household episodes of poliomyelitis virus infection involving 133 young children in a study of the acquisition of natural immunity to poliomyelitis in southern Louisiana from 1953 through 1955 Infections with the 3 serotypes of poliomyelitis virus occurred in children of all ages from 23 days upwards, with no apparent effect of maternally derived antibody and no significant predilection for any age group They occurred throughout the year, but with a marked peak in late summer There were distinct differences in type prevalence in the 2 years 1954 and 1955 and in the various areas in any one year These variations are believed to have resulted from relative deficiencies in type-specific seroimmunity in the preschool-age child population There were also marked differences in the relative predominance of the 3 types of virus in silent immunizing infections as compared with that in clinical infections This was believed to reflect the importance of strain virulence in the causation of disease, type 2 being especially deficient in virulent strains The observations of 1954 and 1955 do not give the same picture of the relative importance of family size and socioeconomic status in their effect on infection rates In 1954, family size seemed to be of greater importance and in 1955, socioeconomic status, but both factors are believed to predispose to early infection

Virus was isolated from at least 92% of infected index children The mean duration of fecal virus excretion was estimated as 51 days Infections in household associates of index children showed a 92% infection rate in individuals previously nonimmune, and a greater than 20% rate of reinfections in immune persons Evidence for reinfection consisted of significant rises in neutralizing antibody titer, demonstration of virus excretion, or both However, because of the relative infrequency with which virus was recovered from reinfected persons, it is felt that reinfection is of little or no importance in virus dissemination Although almost universal infection of the nonimmune members of a household where poliomyelitis virus is introduced is believed to be the rule, a number of examples of abortive household epidemics are cited Closely associated households are usually infected simultaneously or shortly following one another No significant clinical disease was associated with the 244 primary infections and 65 reinfections documented in this study Minor illness was probably associated in 27% A concept of the dissemination of poliomyelitis viruses through the community was presented

Platybasia W Kiær Ugesk læger 119 456 458 (April 11) 1957 (In Danish) [Copenhagen]

The case of platybasia in a man aged 44 with progressive neurological symptoms for 21 years had been interpreted as disseminated sclerosis The changes in the occipital foramen and adjacent bones found at autopsy established the diagnosis of typical platybasia The tendency for basilar impression to masquerade as syringomyelia or disseminated sclerosis is stressed In most cases of platybasia there is a primary anomaly in the development of the base of the skull which, as a rule, does not manifest itself before adult age Paget's disease is thought to be the most frequent cause of secondary platybasia, which is also seen in osteomalacia, hyperparathyroidism, and osteogenesis imperfecta Roentgen examination of the cranium can give a certain diagnosis of platybasia The diagnosis is often missed simply because the disease is not looked for (Scoville and Sherman) The condition can be improved by operative treatment

THERAPEUTICS

Studies of the Use of Glyco-Algin as a Solution for Transfusion T Takayama J Internat Coll Surgeons 27 557-567 (May) 1957 [Chicago]

Glyco-Algin was prepared by dissolving 0 3% sodium alginate in 5% dextrose It was adjusted to maintain a specific viscosity of 2 and a molecular weight of 15,000 Rabbits and dogs were bled at the rate of 20 cc per kilogram of body weight in 6 minutes and per minute, respectively, and Ringer's solution, dextrose solution, alginate sodium chloride solution, and Glyco-Algin were administered as supplementary fluids in equal volumes by slow (drip) transfusion or by rapid transfusion The results obtained with these 4 supplementary fluids were compared and showed that Glyco-Algin is an ideal transfusion solution in that it causes a sufficient increase in blood pressure, maintains the blood pressure at an even level, restores and maintains the circulating blood and plasma volumes, and stabilizes the elimination of urine and the carbohydrate metabolism without changing the level of extracellular fluids The limit of speed of transfusion of a polysaccharide such as Glyco-Algin is 0 6 cc per minute per kilogram of body weight This limit, however, is equivalent to 600 cc per minute in adults, and it is therefore entirely negligible in clinical cases Three hundred reports on the use of Glyco-Algin as a blood substitute in patients admitted to large hospitals in Japan confirmed the satisfactory experimental results

The Combination of Rauwolfia Serpentina and a New Xanthine Derivative in the Treatment of Hypertension T Rodari Minerva med 48 452-457 (Feb 10) 1957 (In Italian) [Turin, Italy]

Sixteen patients with essential hypertension, 14 with renal hypertension, and 10 with hypertension and cardiocirculatory insufficiency were treated with a combination of Rauwolfia Serpentina and a new xanthine derivative The average daily dose was 50 mg of the extract at 8% in total alkaloids of Rauwolfia Serpentina and 600 mg choline theophyllinate The combination had a hypotensive effect in 8 patients with essential hypertension, the systolic pressure was reduced by 30 mm Hg The combination had a beneficial effect on 9 patients with renal hypertension, the systolic pressure went down 30 mm Hg Slight changes were observed in the patients with cardiocirculatory insufficiency, in these patients the diuresis increased from 70 to 80% The pulse rate was reduced in all patients Intolerance or side effects were not observed

Oral Insulin Substitutes L J P Duncan and J D Baird Scottish M J 2 171-182 (May) 1957 [Glasgow]

It is now widely accepted that the toxic potentialities of carbutamide (BZ 55) preclude its clinical use Tolbutamide (D 860), however, in which the amino group of carbutamide has been replaced by a methyl group, may be sufficiently free from undesirable attributes to permit its therapeutic application The long-term effects of tolbutamide or any other hypoglycemic agent which may be produced in the future will have to be critically studied with particular regard to their possible toxic effects, to the feasibility of giving them indefinitely without loss of effect, and to their influence, if any, on the progression of the degenerative complications of diabetes If the answer to these questions should prove satisfactory, then their general therapeutic use would be justified Even then, diabetic patients would still have to restrict their diet and about 50% of them would continue to have satisfactory control by this means alone To substitute hypoglycemic sulfonamide therapy for dietary restriction would be quite unjustified and would merely encourage the persistence or development of obesity However, about 70 to 80% of middle-aged or elderly nonobese patients with relatively mild stable diabetes who, in addition to dietary restriction require a small or moderate daily dose of insulin, would be able to discard their insulin syringes and be treated with tablets taken by mouth Such patients, however, account for only 1 in every 4 or 5 diabetics presently receiving insulin

It should be recognized that the hypoglycemic sulfonamides are merely oral insulin substitutes' for a limited number and type of diabetic patients and they are in no respect 'oral insulins" The administration of insulin itself is still the only treatment to which diabetes will always respond, whatever its type or severity Insulin has withstood the test of time, it is safe and free from toxic attributes, it can be given indefinitely without any loss of effect, and it corrects all the presently known metabolic consequences of diabetes Any alternative for it should possess all these properties, and it is clear that these sulfonamide derivatives are deficient in several respects To be influenced or dominated by the preference of diabetics for a new form of treatment simply because it is more convenient and acceptable than the injection of insulin would constitute a disastrous failure in professional responsibility

In Vivo Effect of Ganglion Blocking Drugs and of Aneurin Administered Separately and in Combination F Manca and D Lolli Minerva ginec 9 193-199 (March 31) 1957 (In Italian) [Turin, Italy]

The effect of the ganglion blocking drugs and of aneurin administered separately and in combination was studied with the sphygmogram in a group of male and female cats of the average weight of 3 kg each The drugs were injected into the femoral vein and at times into the jugular vein The animals were under chloralose narcosis Experiments were carried out with doses of from 5 to 50 mg per kilogram of body weight of hexamethonium, 8 to 16 mg per kilogram of N,N,N'-N'-3-pentamethyl-N,N'-diethyl-3-azapentane-1, 5-diammonium dibromide (Pendiomid) and 3 to 110 mg per kilogram of body weight of aneurin The ganglion blocking drugs caused a depression of the circulation which was more evident the higher the initial pressure The hypotension was more marked the higher the dose injected The effect of the drugs lasted longer when higher doses were administered, the authors think that Pendiomid may have a longer-lasting effect The ganglion blocking drugs increased the sensibility of the animals to adrenalin Tension-regulating centers were still efficient even after the administration of a high dose of ganglion blocking drugs A dose of 3 mg of vitamin B_1 per kilogram of body weight caused in the animals under anesthesia a moderate and transitional drop of the arterial pressure Disturbances of respiration were observed with a dose of more than 20 mg of aneurin per kilogram of body weight and paralysis with a dose of more than 70 mg per kilogram The authors believe that ganglion blocking drugs and aneurin given in combination and in a low dose have a longer, even though not so intensive, hypotensive effect and do not cause a rapid drop of pressure

Antibiotic Combinations Antibacterial Action of Plasma of Normal Subjects After Oral Doses of Penicillin V, Tetracycline Hydrochloride and a Combination of Both W F Jones Jr and M Finland New England J Med 255 869-875 (May 9) 1957 [Boston]

Several definitions of synergism and antagonism have been offered by laboratory workers in their evaluations of the antibacterial or therapeutic action of combinations of antimicrobial agents by comparison with that of their individual components, other terms such as additive, inhibitory, potentiating, and neutral have also been introduced to describe the various types of combined actions Since none of these comparisons can readily be applied to the results of the use of these agents in the therapy of human infections, the authors approached the problem by assaying and comparing in the same subjects the antibacterial action of blood after administration of antibiotics in the same doses singly and in pairs The first pair of antibiotics studied was erythromycin and penicillin, the second pair was penicillin G and oleandomycin This report deals with a third pair—namely, tetracycline and penicillin V in 2 doses (500 mg and 1 000 mg)

Each of 5 normal young men took, in random rotation at intervals of 3 days or more, one or the other total dose of either tetracycline alone or penicillin V alone or equal parts of both Each subject, therefore, received 6 different doses, each dose was taken half an hour before breakfast Blood was obtained before and at the same intervals after each dose over a period of 24 hours, and the plasmas were tested for antistreptococcic and antipneumococcic activity From the data obtained the authors conclude that at any given time after the same total dose the combination of equal parts of tetracycline hydrochloride and penicillin V yielded appreciably less antistreptococcic and antipneumococcic activity and also less antistaphylococcic activity than that which was derived from the same total amount of one or the other individual component The differences in absorption and excretion of the 2 antibiotics used resulted in the best activity from penicillin V alone during the first few hours after the doses, and tetracycline generally yielded the greatest antibacterial activity thereafter, only occasionally and transiently did the combination produce greater activity than that resulting at the same interval from one or the other single agent

PATHOLOGY

Radioisotope Determinations of Blood Volume The Results of More Than 300 Tests W Freeman Am J Clin Path 27 393-400 (April) 1957 [Baltimore]

The circulating whole blood plasma, and cell volumes were determined with use of radioactive iodine incorporated in human serum albumin (Risa) for more than 200 hospitalized patients with serious medical or surgical disease Some 366 such determinations were made The method proved to be practical and safe, and it may be repeated daily without harm to the patient Determinations made with a sample of blood collected 1 minute after the injection of the dilute Risa were more accurate than determinations based on blood collected 5, 10, or 15 minutes after the injection One hundred twenty-two patients (61%) had normal values for whole blood volume, 112 patients (56%) had circulating plasma volumes in the normal range, and 96 patients (48%) had cell volumes that were estimated as normal Twenty-four patients (12%) had deficient whole blood volumes, 18 (9%) had deficient plasma volumes, and 50 (25%) had deficient cell volumes Fifty-four patients (27%) had excessive volumes of circulating whole blood and cells, and 70 (35%) had excessive plasma volumes This indicates that 150 (75%) of the 200 seriously ill, hospitalized patients were in no need of transfusions of any kind

In a person with a labile circulating blood volume, the Wintrobe and Risa hematocrit values, the level of hemoglobin, and the red blood cell count are not dependable indications of the need for transfusion of blood The transfusion of blood or fractions of blood may be disastrous in certain patients The danger is of major importance in patients who can not tolerate an overloaded volume of circulating blood, such as those who have arteriosclerosis, low cardiac reserve, or both Unless the patient is actively bleeding, one should not administer transfusions of whole blood or its fractions before determining the volumes of circulating whole blood, plasma, and cells

The Significance of the Non-specific Inflammation in Auricular Appendages of Patients with Mitral Stenosis C A Wagenvoort Acta med scandinav 157 307-318 (No 4) 1957 (In English) [Stockholm]

One hundred eighteen auricular appendages, removed at valvulotomy from 74 female and 44 male patients between the ages of 11 and 58 years with mitral stenosis, were studied microscopically Special attention was paid to the incidence of nonspecific inflammatory foci in the myocardium, consisting of lymphocytes and large mononuclear cells Such foci were found in 36 specimens (30 5%) and appeared to be associated in most of the cases with thrombosis and auricular fibrillation Aschoff bodies were found in 76 specimens (64 4%) They were observed more frequently in the specimens removed from younger than from older patients There was in general a negative correlation of Aschoff bodies with nonspecific foci, thrombosis, and fibrillation Additional microscopic studies were performed on 22 hearts obtained at autopsy of patients with rheumatic mitral stenosis who had been operated on or not and of patients without heart disease It usually appeared that nonspecific inflammation, if present, was not confined to the left auricular appendage but was also present in other parts of both auricles, even if thrombosis was limited to the left appendage

The author does not agree with the opinion of other workers that nonspecific inflammatory foci in the myocardium are to be regarded as a nonspecific reaction to the presence of an organized thrombus His findings showed that such foci seemed to be more closely related to recent than to organized thrombi, that thrombosis of the auricular appendage may occur without any sign of myocarditis, that these foci appeared to have no preference for the vicinity of a thrombus, and that the inflammatory reaction frequently occurred in other parts of the heart though thrombosis occurred exclusively in the left auricle The author's findings, however, suggest some direct or indirect relation between the various histopathological lesions observed in the auricular appendages on the one hand and auricular fibrillation on the other One could consider that the presence of the lymphocytic infiltration between the muscular fibers, whatever the cause may be, might bring about a disturbance in the stimulus formation resulting in auricular fibrillation Another explanation would be that fibrillation is primary, causing anoxemia of the auricle, and that such anoxemia might bring about an inflammatory reaction

Clinical-Pathologic Study of 76 Cases of Recurrent Graves' Disease, Toxic (Non exophthalmic) Goiter, and Nontoxic Goiter Does a Relation Exist Between Thyroid Hyperplasia and Struma Lymphomatosa? H J Spjut, W D Warren and L V Ackerman Am J Clin Path 27 367-392 (April) 1957 [Baltimore]

Microscopic sections were studied of residual thyroid tissue removed at repeated thyroidectomies in 71 patients and at autopsy in 5 patients The interval between thyroidectomies, or the interval between operation and death, for the entire group averaged 6 years, with a range of from 3 months to 23 years Of the 76 patients, 66 female and 10 male, 35 had Graves' disease, 22 had toxic (nonexophthalmic) goiter, and 19 had nontoxic goiter An attempt to demonstrate convincingly progression of thyroidal hyperplasia to chronic lymphomatous thyroiditis (Hashimoto's disease), chronic thyroiditis, or Riedel's struma, failed The second surgical specimen obtained from a 39-year-old woman with nontoxic goiter showed almost diffuse oxyphilia, lymphoid aggregates with germinal centers, and fibrosis, the first specimen removed 3 years previously had shown a degenerating adenomatous nodule The surrounding parenchyma showed lymphoid follicles with only focal oxyphilia of follicle cells This is the only case in which a diagnosis of chronic lymphomatous thyroiditis was made, it seems likely that, if an early phase of this disease exists, the first specimen has been an example of it and that the second specimen represented the typical appearance of the disease There is no evidence of transition from hyperplasia to lymphomatous goiter

Microscopic changes of severe exhaustion atrophy were observed in the second specimen obtained from 2 patients with Graves' disease, 2 with toxic (nonexophthalmic) goiter and 3 with nontoxic goiter There were foci of oxyphilic cells, lymphoid follicles with germinal centers, lymphoid aggregates, fibrosis that often accentuated the lobular pattern, plasma cells, macrophages, neutrophils, and eosinophils These

7 cases most closely simulated chronic lymphomatous thyroiditis but the outstanding microscopic features which distinguished them from cases of chronic lymphomatous thyroiditis were the different histological stages of involution and usually a lack of diffuse or nearly diffuse oxyphilic change of the follicular epithelium Except for these 7 cases, no distinctly specific microscopic changes that would distinguish the first from the second specimen were noted in the thyroidal remnants of the patients with the 3 types of disease of thyroid gland Lymphoid tissue was seen in thyroid glands of patients with each of the 3 types of thyroid disease, increasing only slightly in the second and third specimens When present in the first specimen it was also present in the second specimen Oxyphilic cells (Hurthle cells) were seen in thyroid glands obtained from patients with each of the 3 disease types and were not correlated with any outstanding alteration in the clinical course The course of exophthalmos could not be predicted from the histological findings The presence of lymphoid follicles in thyroid glands of patients with Graves' disease was associated with a longer interval between operative procedures This was not true for the other 2 disease groups Histological alterations due to therapeutic agents could not be evaluated because most patients had been treated with more than 1 agent, and the doses used and the duration of treatment varied

Relation Between Pyelonephritis and Bacterial Counts in the Urine An Autopsy Study R A MacDonald, H Levitin G K Mallory and E H Kass New England J Med 256 915-922 (May 16) 1957 [Boston]

The clinical diagnosis of pyelonephritis is often overlooked due to the absence of overt clinical manifestations of pyelonephritis in many patients Bacterial counts of the urine have been performed in an attempt to add to the objective methods for determining the presence of infection of the urinary tract Clinicians have long been aware of the fact that clinically evident infections of the urinary tract are accompanied by sufficiently large numbers of bacteria to permit them to be found readily upon microscopic examination of the urinary sediment Similarly, the urines of patients in whom a clinical diagnosis of active pyelonephritis is made have almost invariably been found to contain more than 100,000 bacteria per milliliter The authors performed bacterial counts of the bladder urine in 100 unselected autopsies and correlated them with the pathological data Forty per cent of the urines obtained at autopsy by needle aspiration of the bladder contained more than 100,000 bacteria per milliliter 53% contained no bacteria, and 7% contained between 10 and 10,000 bacteria per milliliter Active pyelonephritis was found in 14 of the 40 patients with 100,000 or more bacteria per milliliter of urine (who were considered to have true bacteriuria) and in but 3 of 60 patients with no or relatively few bacteria Three cases of acute cystitis without pyelonephritis were encountered, all were associated with 100,000 or more bacteria The predominant micro-organism in the urine at autopsy was Aerobacter aerogenes, and there had been little tendency for the organism to disappear with treatment in the patients studied

Antimicrobial therapy was given up to at least 24 hours before death in 60 to 70% of patients, but the beneficial effects of such therapy on the course or frequency of pyelonephritis were limited Healed pyelonephritis occurred in 18% of patients, and the prevalence of this lesion bore no relation to that of bacteriuria A total of 33% of the patients gave evidence of active or healed pyelonephritis Benign prostatic hypertrophy was associated with bacteriuria in only 9 of 26 patients in whom the prostatic lesion was found and active pyelonephritis that was associated with benign hypertrophy occurred only in association with bacteriuria A substantial correlation between bacteriuria, pyelonephritis, and inlying catheterization was demonstrable Clinical diagnosis of active infection of the urinary tract was not made in 70% of patients in whom active pyelonephritis occurred In many of those in whom the diagnosis was not suspected extensive pyelonephritis, sufficient to be a major cause of death, was found Such evidences of infection of the urinary tract as pyuria, azotemia, the presence of granular casts and albuminuria are not reliable indexes of the presence or absence of bacteriuria or of active pyelonephritis No relation between hypertensive heart disease, cardiomegaly, or elevated diastolic pressures and bacteriuria was demonstrable It is concluded that bacterial counts are a reliable means for detecting true bacteriuria and that such bacteriuria is often associated with active infection of the kidneys and other structures of the urinary tract

Neuroblastoma and Related Tumors S Lindsay and I T Chaikoff A M A Arch Path 63 451-459 (May) 1957 [Chicago]

An attempt was made to clarify the interrelations of the tumors of the sympathetic nervous system A series of 236 patients were studied Follow-up examinations were made on 206 and completed on 87 According to histological and cytological criteria the tumors were divided into 3 groups neuroblastoma ganglioneuroblastoma and ganglioneuroma The symptoms manifested by neuroblastoma and ganglioneuroblastoma were essentially alike They were gastrointestinal (49%), respiratory (20%), skeletomuscular (20%), hemic (20%), dermal (8%), and urinary (2%) Only 8% of the 121 patients had no symptoms, the tumor was discovered on physical or x-ray examination Forty per cent of the 109 patients with ganglioneuroma had symptoms referable to the tumor Almost all of these tumors were respiratory and occurred in patients with mediastinal neoplasms All tumors in this group were benign

Congenital neuroblastoma occurs within the first 6 years of life and is fatal in 70% of the cases The ganglioneuroma is a benign tumor and occurs chiefly in adults The ganglioneuroblastoma is a tumor which combines features of both normal ganglionic tissue and neuroblastoma It is likely to be a manifestation of either a lower degree of malignant degeneration of a neurogenic sarcoma or a partial degree of differentiation of a neuroblastoma It is fatal in 69% of the cases A differentiation between these tumors appears justifiable because of the real differences in their biological behavior

BOOK REVIEWS

The Principles and Methods of Physical Diagnosis Correlation of Physical Signs with Certain Physiological and Pathological Changes in Disease By Simon S Leopold M D, Professor of Clinical Medicine, School of Medicine and Graduate School of Medicine, University of Pennsylvania, Philadelphia With chapter on Sounds from the Thorax Acoustic Principles, by S Reid Warren, Jr Sc D Professor of Electrical Engineering, Moore School of Electrical Engineering, University of Pennsylvania Second edition Cloth $9 Pp 537, with 404 illustrations W B Saunders Company, 218 W Washington Sq Philadelphia 5 7 Grape St, Shaftesbury Ave London, W C 2 England, 1957

In this day when there are cries that too much dependence is placed on laboratory diagnosis, a book that stresses what can be learned by questioning and by the use of eyes, ears, and sense of touch is welcome Bedside diagnosis is still an important part of medical practice, and physical diagnosis is something about which the undergraduate or the practitioner can not learn too much Basic understanding plus practice and experience are essential to practice in any field This book, without wasted words, in interesting style, provides the essentials of physical diagnosis Many illustrations, some of them in color, supplement the written word When used with the teacher's lecture or for independent reference, this book should provide much helpful guidance

Retirement A New Outlook for the Individual By Gifford R Hart Cloth $3 95 Pp 179, Harcourt, Brace & Company, 383 Madison Ave, New York 17, 1957

This book apparently is intended to help persons to look forward to retirement and to plan for it Many wait until the day for retirement arrives before they give much thought to it As a result, they often feel lost and unhappy Those who have planned for what can be one of the most enjoyable parts of the span of life can find many things that can keep them busy and happy and perhaps as productive as at any time of their life The author of this book sets forth some interesting philosophy on this subject, and he makes his points with few wasted words and yet with a style of presentation which is interesting and provocative

The Diagnosis and Treatment of Endocrine Disorders in Childhood and Adolescence By Lawson Wilkins M D, Associate Professor of Pediatrics Johns Hopkins University Baltimore Second edition Cloth $17 50 Pp 526, with illustrations Charles C Thomas, Publisher, 301-327 E Lawrence Ave Springfield Ill, Blackwell Scientific Publications, 24-25 Broad St, Oxford, England Ryerson Press, 299 Queen St, W Toronto 2B, Canada, 1957

This is an extensive revision and expansion of the first edition which appeared in 1950 and which has become a classic in pediatric endocrinology In this revision the general pattern of presentation of the subject by means of case reports is followed as in the previous edition, but the theoretical background of the subject has been greatly enlarged so that the present volume may truly be classed as a textbook on pediatric endocrinology Of particular interest are the expanded discussions of sex chromatin, metabolism, the adrenogenital syndrome, the abnormalities in gonadal function, and a newly added chapter on diagnostic methods Differential diagnosis is stressed The author has made notable contributions in this field The book is well written, beautifully illustrated with original pictures of clinical material, and artistically printed This volume should be in the hands of all those engaged or interested in the treatment of endocrine disorders and can be recommended as the most authoritative and up-to-date presentation of the subject available

The Eye in General Practice By C R S Jackson, M A B M, B Ch, Ophthalmic Surgeon Royal Infirmary, Edinburgh Cloth $5 Pp 152 with 25 illustrations E & S Livingstone Ltd, 16 and 17 Teviot Place, Edinburgh 1, Scotland [Williams & Wilkins Company, Mount Royal and Guilford Aves, Baltimore 2] 1957

This little volume, a condensed version of a classic textbook on ophthalmology of 10 years ago, was compiled with the special needs of the general practitioner in mind, and it also is just what is needed for nurses, school teachers, optometrists opticians, and parents, for it gives in clear language the pertinent facts about the eye and its disorders Anatomy, physiology and mathematical optics are barely touched on and then only in terms familiar to lay persons Only the most common of eye diseases are mentioned There is no mention of indications for surgery' nor directions for treatment of any disorder The chapter on diseases of the eye is short but excellent for first aid attendants, school physicians, and country doctors who must be able to care for the simple disorders and leave the complicated cases to the specialist with modern hospital facilities A short chapter on the eye in diseases of other parts discusses briefly but comprehensively the role of the eye in diseases of the cardiovascular system and in intracranial, endocrine, and metabolic disorders and other conditions The last chapter deals with administrative problems of the local British Public Service to the visually handicapped The book is the answer to the inquiry of the high school student who writes, please send me all information about the eyes as I'm writing a paper"

The Specialties in General Practice Edited by Russell L Cecil, M D, and Howard F Conn M D With articles by William A Barnes M D and others Second edition Cloth $16 Pp 780 with 76 illustrations W B Saunders Company, 218 W Washington Sq Philadelphia 5, 7 Grape St Shaftesbury Ave London W C 2 England, 1957

This second edition shows the results of the editors' devoted attention to the audience for which the volume is intended Various specialists have contributed, always with the general practitioner in mind The book is intended as a handy reference book and contains brief descriptions of various problems encountered in the fields in which the general practitioner usually

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated

works It is not complete for the various specialties nor is it intended to be, as only the less serious but more commonly encountered problems are discussed The book is amply illustrated and is offered in an easy-to-read style so that the reader, whether he is looking up something in minor surgery, orthopedic surgery, pediatrics, psychiatry, or any other subject, will not feel that he is "wading" through some deeply technical material but rather is receiving practical guidance for quick assimilation

Diagnosis and Treatment of Cardiovascular Disease Volumes 1 and 2 Edited by William D Stroud, M D F A C P Professor of Cardiology, University of Pennsylvania Graduate School of Medicine, Philadelphia, and Morris W Stroud III M D, Associate Professor of Medicine Western Reserve University, Cleveland Contributors Edgar V Allen, M D, and others [Fifth edition] Cloth, loose leaf $35 Pp 719, 1001-1702, with illustrations F A Davis Company 1914-16 Cherry St, Philadelphia 3, 1957

This loose-leaf presentation is edited by well-known cardiologists who have received the help of about 60 contributors, each an expert in his own field The present edition represents an attempt to bring the volumes up to date, the loose-leaf binding being used to permit continuous revision This is an excellent book for the student or practitioner, whether he be in general practice or a specialty The book is amply illustrated, has been prepared with a pleasing type, and has a complete index Of great interest to those who like to peruse the literature will be the lists of references at the end of many of the chapters, some are extremely complete

Basic Nutrition By E W McHenry, M A, Ph D, F R S Professor of Public Health Nutrition, School of Hygiene, University of Toronto, Toronto Cloth $5 Pp 389, with 9 illustrations J B Lippincott Company 227-231 S Sixth St, Philadelphia 5 2083 Guy St, Montreal, Canada, Pitman Medical Publishing Company Ltd, 45 New Oxford St, London W C 1, England 1957

More useful information is contained in this book than is generally found in similar textbooks prepared for university or nursing students This usefulness stems, no doubt, from the intent of the author to avoid generalities The material has been prepared with the basic assumption that human requirements for nutrients do not vary with race or nationality, when treating differences in nutrient requirements in health and diseases, one must also consider the geographical region and environment This book was prepared to enable the reader to adapt the specific information given to his own particular circumstances This approach should make the book a valuable reference for those who have either a casual or working relationship with nutrition It is a well-documented and up-to-date book, but, in addition to the basic-seven food groups, reference might well have been made to the concept of four groups recently introduced in this country by the United States Department of Agriculture

After a thorough introduction to the utilization, requirements, and sources of the important nutrients, the author discusses the practical application of the knowledge The physician concerned with nutrition should be especially interested in several of the later chapters There is a concise chapter on special diets followed by one on the evaluation of nutritional conditions A discussion of studies of food intake, determination of nutritional status, and biochemical methods for the appraisal of nutritional status will be found in the latter chapter The final chapter, which has world-wide significance, is concerned with the causes and prevention of malnutrition This chapter and a table of the composition of foods conclude this fine work on basic nutrition

Clinical Roentgenology of the Digestive Tract By Maurice Feldman M D, Assistant Professor of Gastroenterology, University of Maryland, Baltimore Fourth edition Cloth $15 Pp 776 with 728 illustrations Williams & Wilkins Company, Mount Royal and Guilford Aves, Baltimore 2, 1957

The revision of this standard reference in roentgenology of the digestive tract has been extensive It incorporates the newer developments in this field since the last edition, eight years ago All of the digestive tract, its associated organs and its environment are discussed The mode of presentation is that established in the preceding edition Not only are the roentgenologic findings emphasized but the pathological, surgical, and clinical aspects are also considered Numerous rare conditions, information about which is obtained with difficulty from other sources, are described Each subchapter is followed by a bibliography Statistical information is available for most of the disease processes Only the essentials regarding methods are given The illustrations, though not numerous, should be adequate Double column format is used This book should be useful to the internist for whom it was primarily written Roentgenologists will find the comprehensive nature of the material a valuable addition to the reference library This book, in view of the central role of roentgenology in the diagnosis of the gastrointestinal diseases, may well be recommended to every physician who is interested in this field

The Ciba Collection of Medical Illustrations Volume 3 A Compilation of Paintings on the Normal and Pathologic Anatomy of the Digestive System Part III Liver, Biliary Tract and Pancreas Prepared by Frank H Netter, M D Edited by Ernst Oppenheimer, M D Cloth $10 50 Pp 165, with 133 color plates Ciba Pharmaceutical Products, Inc, 556 Morris Ave, Summit N J, 1957

This volume represents a compilation of paintings and colored drawings of the normal and pathological anatomy of the organs mentioned On each page, next to the illustration, is a concise explanation Chapter subjects include normal anatomy, physiology and pathophysiology, hepatic and pancreatic function tests, diseases of the liver, diseases of the gallbladder and bile ducts, and diseases of the pancreas The text and illustrations have been prepared in consultation with Oscar Bodansky, Eugene Clifton, Donald Kozoll, Hans Popper, and Victor M Sborov These outstanding authorities add to the stature of the book The illustrations are clear, instructive, and well printed They cover, in a relatively comprehensive fashion, the subjects involved, although illustrations of this sort may depart, in certain instances, from the situation observed in photographs This book should serve a useful purpose, particularly as a teaching medium and also as an instructive volume, for anyone interested in the field

QUERIES AND MINOR NOTES

TREATMENT OF CHRONIC VARICOSE ULCERS

To the Editor —*Kindly comment on the treatment of chronic, recurring varicose ulcers by using plasmin, a blood plasma enzyme Is this similar to preparations of trypsin?*

E G Hubin, M D Sandstone, Minn

Answer —When a varicose ulcer fails to heal or keeps recurring, a variety of factors need to be considered Most frequently one finds a postphlebitic ulcer, which rides on an incompetent perforator vein and is surrounded, nay strangled, by a fibrous ring and lymphatic stasis When such ulcers are widely excised, the offending perforators are ligated flush with the deep fascia, and a three-fourths-thickness skin graft heals well and firmly but necessitates at least three weeks of bed rest Additional venous segments creating congestion may need to be stripped Chronic leg ulcers may also fail to heal because of arteriolar sclerosis with or without hypertension Sympathectomy may help, but naturally some metabolic disorders, such as diabetes or lipemia, need to be controlled

When it comes to local treatment, necrotic bases may be digested with streptokinase, trypsin, or plasmin The latter, frequently called fibrinolysin, is the fibrinolytic enzyme of the blood, which, when activated, does dissolve clots and necrotic tissue In the gangrenous heels of diabetics, enzymatic dédridement does yeoman's service If, however, the underlying cause of the ulcer is a high postural venous pressure, the skin will break down again until the incompetent perforators are eliminated

PENILE DEFORMITY AFTER TRANSURETHRAL PROSTATECTOMY

To the Editor —*A 56-year-old man had a transurethral prostatectomy two years ago, followed by angulation deformity of the proximal third of the penis eight months later He received a number of corticotropin (ACTH) injections, with no benefit British physicians are said to have some gadgets to straighten the penis so that a patient can have coitus What can be done now?*

S L Betagole, M D, Cincinnati

Answer —The deformity described which occurred after transurethral prostatectomy usually is caused either by postoperative stricture of the urethra or by the development of plaques in the corpora cavernosa known as induration of the corpora cavernosa (Peyronie's disease) If a no 24 sound passes through the urethra easily, the stricture, of course, is eliminated Treatment for this disease often is unsuccessful External application of radium probably gives the best results One would question the efficaciousness of any gadget that would straighten out penile deformity

RECURRING INFECTIOUS THROMBOPHLEBITIS

To the Editor —*A woman, aged 53 years, recently developed a slight pain in the right calf This gradually grew worse and became painful on walking Three weeks after the onset she developed chills, her temperature was 101 F (38 4 C), and there was severe pain on the right side of the lower chest over the liver She had no cough She was hospitalized and the right leg elevated Treatment consisted of hot applications to the leg and the administration of Achromycin (by mouth), heparin, and Dicumarol X-ray of the chest showed involvement of the right lower lobe, and there was a pleural-like friction sound on the right side of the lower chest After two weeks of treatment the symptoms in the lung disappeared and the pain in the leg was not so severe, the temperature was normal Two days later the patient was allowed to sit up for an hour in the morning and the afternoon and was made to walk a few times about the room Two days after she was up and walked she had a relapse, with severe pain in the leg and inguinal region on the right side, nausea, chills, temperature of 101 F, and a feeling of pressure over the urinary bladder with frequent urination (every half hour) She was put to bed for three weeks, the foot of the bed being elevated and hot applications being applied to the right leg At the end of that period she was completely without symptoms and was discharged from the hospital, with instructions to stay in bed most of the time One week after the patient went home she got up to entertain a friend She stayed up several hours and walked up and down the stairway several times The next day she had a relapse, with severe pain over the bladder, frequent urination, pain in the leg, and a temperature of 100 F After she stayed in bed four to five days, the symptoms disappeared again Now, if she stays up very long, she develops pains over the bladder and has to urinate frequently At present she wears elastic stockings when she gets up As long as she stays in bed, she is asymptomatic She takes Dicumarol, 50 mg every other day The right leg is still swollen Please explain the pain and pressure feeling over the bladder with frequent urination How long will it take for the swelling in the leg to disappear, and when will she be able to do any kind of work and be free of the above symptoms? Is it advisable to discontinue the administration of Dicumarol? At present, the prothrombin time is 20% of normal Please suggest another treatment for this condition*

D J Louis, M D, Chicago

Answer —In this case one is dealing with a patient who presumably had three episodes of recurring infectious thrombophlebitis With the first attack, she had a pulmonary infarction Subsequently, there was a history of recurring bouts of chills and fever when the patient resumed activity This also was associated with pains in the suprapubic region and frequent urination

---

The answers here published have been prepared by competent authorities They do not however, represent the opinions of any medical or other organization unless specifically so stated in the reply Anonymous communications and queries on postal cards cannot be answered Every letter must contain the writer s name and address, but these will be omitted on request

The frequency of urination and the discomfort in the suprapubic region may not necessarily be due to the thrombophlebitis It is quite possible that the patient has some infection in the urinary tract This may be in the bladder itself or in the kidneys The possibility of a pyelitis or pyelocystitis cannot be excluded until further studies are carried out, such as examination of the urine sediment and culture and cystoscopic examination, in many cases, a pyelogram may be helpful The repeated bouts of chills and fever could very well be due to some infectious condition of the urinary tract If any of the findings are present, then broad-spectrum antibiotics, such as Furadantin, 50 mg four times a day after meals and at bedtime, or Gantrisin may be helpful

The swelling of the leg is most likely due to the recurring infectious thrombophlebitis, and this patient may be developing a chronic phlebitic syndrome An elastic support should be recommended, and its use should be continued for an indefinite period, particularly when the patient is on her feet and walking about The swelling may continue for some length of time However, it may be controlled if intensive overall treatment is instituted This consultant is partial to giving Mecholyl iontophoresis for a series of 10 treatments and use of the oscillating bed, if available The patient should also continue receiving vasodilators, such as Priscoline, 25 to 50 mg three times a day before meals, or Arlidin, 6 mg three times a day before meals and papaverine, 1 or 1½ grains (60 or 100 mg) four times a day after meals and at bedtime If the condition persists, it is suggested that one of the enzyme preparations, either Parenzyme or Chymar, 5 Gm daily for a series of 10 treatments, be injected intramuscularly The patient should be advised to sleep with the feet elevated, and smoking obviously is interdicted The patient is permitted to resume work after three or four weeks of therapy and two weeks of convalescence

The administration of Dicumarol is recommended for three to six months, depending upon the progress of the patient Should the episodes of chills and fever be proved to come from some bladder infection, then the treatment may be discontinued, however, if it is decided that these symptoms are definitely recurring phlebitis attacks, then it should be continued for at least three months or longer, if necessary Needless to say, the dosage of Dicumarol will be guided by the prothrombin time, which should be determined once a week or every 10 days In hospital patients, 20% levels are optimal, however, when a patient is ambulant or is not under daily supervision, then levels of 30% or even 40% would be satisfactory In the high levels, 50-mg doses are recommended In levels in the 20s, 25 mg is preferred in order to avoid side-effects

As for further treatment, this has practically been answered in the above paragraphs antibiotic therapy, particularly directed toward any possible infection, either in the bladder or elsewhere, treatment of the vein disorder with anticoagulants, elevation of the foot, and an elastic bandage or stocking for support, and injection of an enzyme preparation intramuscularly, if indicated If the condition is not controlled, should pulmonary infarction occur, or if the patient still has episodes of recurrence, then the advisability of surgery should be considered, the veins in the thigh being exposed for ligation and resection

GLUCOSE TOLERANCE TEST AFTER GASTRECTOMY

To the Editor —*A 28-year-old man had a fasting blood sugar level of 103 mg per 100 cc A glucose-tolerance test made later in March, 1957, was as follows*

Time a m	*Sugar in Blood, Mg /100 Cc*	*Sugar in Urine*
8 (fasting)	*107*	*None*
8 35	*224*	*Faint trace*
9 05	*325*	*3 3%*
10 05	*157*	*1 0%*
11 05	*58*	*None*

There is a history of duodenal ulcer for the past 10 years, of gastrectomy in 1953, and of acute pancreatitis two years prior to writing Is this condition diabetes mellitus, or can it be due to chronic pancreatitis? In the question of treatment, is a high-protein, fat, and restricted sugar diet indicated for each meal? Should further diagnostic procedures be carried out?

Norman Schaefer, M D , Bronx, N Y

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —This abnormal glucose-tolerance test might well be due to the previous gastrectomy, with rapid emptying of the stomach and accelerated absorption of glucose from the small intestine It would be advisable to perform an intravenous glucose-tolerance test in order to eliminate the factor of absorption One third gram of glucose per kilogram of standard body weight is injected as a 50% solution intravenously over a period of two minutes Specimens for testing are taken from the opposite arm In normal individuals, the blood sugar level returns to normal in 60 to 90 minutes If the intravenous test should prove to be abnormal in this case, it would probably mean diabetes mellitus, but the test would not distinguish between spontaneous diabetes and that due to pancreatitis If the intravenous glucose-tolerance test should reveal diabetes, restriction of dietary carbohydrate would be indicated, provided that examination of the feces did not show defective absorption of fat and protein, which might come about as a result of pancreatic deficiency If such deficiency were found to exist, the restriction of carbohydrate would have to be modified so as not to present the intestine with excessive amounts of protein and fat

Answer —Interpretation of such a glucose-tolerance curve as is presented in this query is made difficult by the history of gastrectomy and acute pancreatitis It is well known that, in some patients, with or without the dumping syndrome, after gastrectomy, the blood sugar level may rise rapidly after the taking of glucose to a point above normal and then return to normal or even subnormal levels at the end of two hours This has usually been interpreted as due to the rapid absorption of glucose because of the rapid delivery of glucose into the duodenum and a corresponding stimulation of insulin production with the later hypoglycemia It would be of value, therefore, in the patient in question to carry out an intravenous glucose-tolerance test. Glucose is administered by vein at the rate of 0.5 Gm. per kilogram of body weight per one-half hour. It may be given as a 20% solution in sterile water or saline solution. The blood sugar level is determined in the fasting state and again at 30, 60, 90, 120, and 180 minutes. The blood sugar level should be returned to normal after 90 minutes. In a diabetic the blood sugar level would remain elevated.

The glucose-tolerance test, as given, may be interpreted as definitely abnormal, since the peak of the curve is far above normal and there is no return to the normal fasting level at the end of two hours. The fact that the blood sugar level at the end of three hours has reached 58 mg. per 100 cc. is of some interest. If the blood sugar level is a "true" glucose value, then 58 mg. is not surprisingly low. On the other hand, if the Folin-Wu method has been employed and the blood sugar level is not a "true' glucose value, then 58 mg. is definitely low. One wonders whether the patient has ever had symptoms suggesting hypoglycemia and whether the patient might have functional hypoglycemia. If this were proved, then a five-meal schedule might be needed.

If an intravenous glucose-tolerance test is confirmatory, the diagnosis of true diabetes mellitus is necessary, possibly on the basis of the preceding pancreatitis. Treatment with a planned diet is indicated. The total calories should be planned for the patient's age, weight, and activity. In general, a diet providing for carbohydrate (150-200 Gm.), protein (80-120 Gm.) and fat (70-100 Gm.) might be employed. In a patient 28 years of age, insulin should be used, unless the patient can be kept under constant observation and can be shown to be free from glycosuria and hyperglycemia on the dietary regimen.

TREATMENT OF CORNEAL DYSTROPHY

To the Editor:—*A patient, 61 years of age, has had corneal dystrophy in his left eye for three years, with progressive worsening of vision. Recently he was told that this condition was developing in his right eye. His work places a heavy load on his vision, and in addition, he must do a considerable amount of automobile driving. What is the latest information on the treatment of corneal dystrophy?*

M.D., Pennsylvania.

This inquiry has been referred to two consultants, whose respective replies follow.—Ed.

Answer.—Dr. F. W. Stocker has reported the use of the inhibitor of carbonic anhydrase, acetazolamide (Diamox), for the endothelial type of corneal dystrophy of the Fuchs type, which this would seem to be. Relatively small amounts of acetazolamide are given over a long period of time, and a clearing of the media is claimed to occur indefinitely as long as the therapy is maintained. A second treatment, which has given good results in many cases, is the transplantation of the cornea. It is important that this transplantation be done as early as is feasible, so that the least amount of destruction of the corneal stroma will be permitted to occur. The latest histological studies show that corneal dystrophy is due to hypertrophic changes in the nerves in the original cornea, and it is quite possible that the steroids, such as prednisone, would help in clearing the opacities caused by the dystrophy. It must be remembered that one is dealing with a destructive lesion of the cornea of unknown etiology, and, therefore, much time must be allowed before any changes can be seen to take place.

Answer.—There are many types of corneal dystrophies, the medical treatment of which is invariably unsatisfactory. There is no known medical treatment that will alter the progress of the more commonly seen corneal dystrophies, such as the nodular dystrophy of Groenouw, the lattice-like dystrophy of Haab-Dimmer, or the spotted, familial type of dystrophy of Fleisher-Fehr. The treatment of choice for these dystrophies is surgical when vision becomes so impaired as to warrant a penetrating corneal transplant. Attempts have been made to treat primary lipid dystrophy medically but with questionable success. In this regard, roentgen irradiation of the cornea has been attempted to arrest the progress of the fatty lesion, and beta-irradiation has been effective in reducing the vascularization and arresting the secondary fatty infiltration. Surgical excision of the corneal nodules seen in Salzmann's nodular corneal dystrophy has been attempted with success by a lamellar or partial penetrating corneal excision with or without a transplant. Endothelial-epithelial dystrophies are usually not amenable to medical treatment and may ultimately require corneal transplantation with a graft large enough to take to healthy endothelium. Advanced epithelial dystrophy accompanied by severe pain has been relieved by a Denig graft with buccal mucous membrane. Resection of the greater superficial petrosal nerve to interrupt the efferent arc of the tearing reflex causes a permanent hypertonicity of the precorneal film by lessening the serous element of the tears. The precorneal film cannot become diluted by the excess of tears usually present in this condition. Deep roentgen therapy to the lacrimal gland has been advocated to alter the secretion of tears in patients unable to withstand surgery. The treatment of marginal dystrophy is usually directed toward correction of astigmatism. Cauterization or excision of the ectatic cornea, with reinforcement of the wound by a conjunctival flap, may be required in severe cases.

RHYTIDECTOMY

To the Editor:—*Is there an effective operation for face lifting so that the heaviness that appears just above and under the cheek bone will disappear? Is such a procedure difficult? Does the condition recur after surgery, and, if so after about what interval of time?*

M.D., Illinois.

Answer.—Rhytidectomy, often referred to as face lifting, is a well-established, effective surgical procedure. When performed for removal of redundant skin of the face and neck, it produces very satisfactory improvement in the appearance but should be done conservatively to prevent a pulled expression to the face. It is a lengthy procedure, when done correctly, requiring three to four hours on the operating table. Since wide undermining of the skin is required, this operation should not be attempted by one who is not thoroughly familiar with the anatomy of the face and neck or by one who is not thoroughly trained in plastic surgical procedures.

It is thought that relaxation of the skin during the aging period is due primarily to a loss of tone in the elastic fibers of the dermis with the muscles of expression playing a secondary role. Although the gain from the surgery is permanent it does not affect the aging process and eventually the skin will again become redundant. The rapidity of the aging process in the skin varies greatly among individuals and therefore some will achieve more lasting improvement than others. The operation may be repeated as often as indicated, the average interval of time being five to seven years.

X-RAY EXPOSURE AND POLYCYTHEMIA

To the Editor.—*A male x-ray technician aged 31 years, has worked in a diagnostic x-ray department of a general hospital for 10 years. Usual safety precautions and intelligent supervision under radiologists have been in force but film badge service has only recently been started and results from this are not yet available. The technician has no complaints whatsoever and physical examination by an internist indicates no abnormality. However, routine blood studies in 1954 and 1956 showed hemoglobin levels of 91% and 100% (16 Gm. per 100 cc.). The white blood cell count was 9,050 and 10,000 per cubic millimeter at these times. In March 1957 the white blood cell count was 9,250 per cubic millimeter and the hemoglobin level was 109% (17.4 Gm. per 100 cc.). A repeat study a week later showed 10,750 white blood cells per cubic millimeter and identical hemoglobin level with a hematocrit of 48%. Differential count showed eosinophils 1%, stab forms 7%, mature neutrophils, 54% and lymphocytes 38%. A week later in an internist's office where a freshly calibrated instrument was used the hemoglobin level was reported as 16.35 Gm. per 100 cc. and the hematocrit as 42%. Should an early polycythemia vera be suspected with these findings? Are further studies indicated? Should the blood studies be done monthly for a period before attempting marrow study?*

Clarence P. Chrest, M.D., Kalamazoo, Mich.

Answer.—The data presented do not indicate that this patient has any evidence of polycythemia. The two hematocrit values are both within normal limits as are the rest of the details of the patient's blood cell count. There is no evidence that x-ray exposure results in polycythemia vera. Patients with polycythemia vera may develop leukemia, and some workers in the field believe that exposure or treatment by irradiation will result in a higher incidence of leukemia in patients with polycythemia vera than treatment by phlebotomies. However, there is no good proof of this view. Certainly in the case described there is no indication that this patient has polycythemia vera, and, moreover, as mentioned above, there is certainly no evidence that there is any relationship between irradiation and the occurrence of this disease.

MALATHION INTOXICATION

To the Editor.—*A 57-year-old woman has a peculiar mottling of both lungs and suffers from periodic respiratory infections which respond to penicillin. She has been a grower of African violets and has several hundred plants in her cellar on which she uses a toxic spray. Could the mottling of the lungs be due to inhaling this toxic substance whose generic name is malathion? Is there any record of toxic effects from constantly inhaling malathion in an enclosed space such as a cellar?*

J. Elmer O'Brien, M.D., Erie, Pa.

Answer.—Malathion is an organic phosphorus insecticide used in the control of certain pests of fruits, vegetables and ornamentals. As a public health pesticide, it has been employed for the control of house flies and as a mosquito larvicide. The usual cholinergic signs and symptoms are characteristic of malathion intoxication. In addition acute muscle weakness has been noted in chickens given large subcutaneous doses of the compound. A detailed discussion of this syndrome is given by Durham, Gaines and Hayes (*A. M. A. Arch. Indust. Health* 13:326-330 [April] 1956). The toxicity of malathion to experimental animals is low as compared with that of many other organic phosphorus insecticides. Based on studies with experimental animals, both the acute oral and the dermal toxicities of malathion are less than those of DDT. No established cases of human poisoning from malathion are known that parallel the circumstances described in the query. No information is available that mottling of the lungs has been associated with inhalation of this or related materials.

FISSURING OF NAILS

To the Editor.—*Please give advice regarding fissuring and splintering of the nails. Is gelatin or tincture of white iodine of any value?*

Sidney Schreider, M.D., Berwyn, Ill.

Answer.—Fissuring and splintering of the nails is sometimes a syndrome per se, other times it is related to various skin diseases and to contacts. In the last named instance it is most essential to eliminate any contacts responsible for keeping the nails in this condition. The syndrome per se sometimes occurs in psoriasis. In cases in which the physical examination was negative (and no doubt the findings of the blood chemistries [uric acid] were normal), gelatin has been used by a number of observers. The latest such report by Rosenberg and Oster indicates that 26 out of 3 patients improved very strikingly. Five cases were definitely associated with psoriasis. Gelatin, of course is an extract of beef and contains amino acids and a goodly percentage of glycine which is capable of increasing peripheral temperature. The results from the use of gelatin have not been uniform among observers. Yet in some cases it has definitely been of help although it has not altered the primary condition, such as psoriasis. Tincture of white iodine has also been used by lay people, but from the scientific point of view it is of no particular merit, having very feeble bacteriostatic and fungistatic properties.

PROBLEMS IN REGULATING REDUCING PILLS

Because of an adverse federal court decision, two government regulating agencies are finding it difficult to proceed against misleading advertising for weight-reducing products when the products themselves cannot be shown to be dangerous

Problems of the Food and Drug Administration and the Federal Trade Commission were related to a subcommittee of the House Government Operations Committee at the conclusion of a week's hearings on weight-reducing products and other medicine and devices that are sold under exaggerated claims

Earlier, medical witnesses agreed that the weight reducers in themselves could not result in loss of pounds, as claimed in ads, and that in some cases they were an actual health hazard to certain persons Dr Leon Hirsh of Cincinnati, who has written and done research on obesity, explained that those containing phenylpropanolamine are among the pills presenting potential dangers, as they could cause coronary attacks or cerebral hemorrhage in some people

George P Larrick, FDA commissioner, said the agency could act if the product is misbranded either by its label or by material accompanying it He said the last action against a weight reducer containing a dangerous ingredient was concluded successfully 13 years ago and that now "the dangerous type of reducing preparation has all but disappeared completely from the scene"

However, the government was unsuccessful in court action against a preparation containing candy and vitamins, which the agency claimed was misbranded in that it was advertised as effective, in itself, in causing loss of weight The judge decided the advertising claims were not unduly exaggerated, as consumption of these pills before a meal would cause some loss of appetite

Because of this and a similar adverse decision, Mr Larrick said, "the Food and Drug Administration was forced to conclude that regulatory action in this field must be very carefully selected and that it would not be feasible to bring cases where the labeling claims were of a qualified nature However, we are preparing to proceed against the promoters of an article falsely represented for weight reduction we are proceeding with caution in the selection of cases and the development of convincing evidence"

Sigurd Anderson, head of the Federal Trade Commission, which can act against any false or misleading advertising (FDA is restricted to labeling and accompanying material), told the commission that his agency's activities also are restricted by the adverse decisions 'Our regulation of the products sold as appetite depressants has been limited largely to claims implying that the product itself has an effect on metabolism, claims of weight loss in definite and predetermined amounts, or special claims such as official government approval of the product"

He had one other complaint The FTC had asked $33,500 more for scientific investigations and testing during the current fiscal year, but it was cut from the budget by Congress

The subcommittee had no plans to urge remedial legislation before adjournment, but will make its recommendations to the full committee when Congress reconvenes in January There is a possibility that Chairman John Blatnik (D, Minn) will investigate tranquilizers some time in the fall

COMMITTEE CONCLUDES HEARINGS ON AUTO SAFETY BELTS

When Congress reconvenes in January it will have before it the findings of a special House subcommittee on the controversial question of whether the federal government should move into the picture by setting standards for auto safety belts and requiring that all cars be equipped with them

The traffic safety subcommittee of the House Interstate and Foreign Commerce Committee conducted almost two weeks of hearings on the subject, taking testimony from physicians, independent researchers, spokesmen for the federal government, and industry representatives With one exception they all endorsed in general the use of safety belts, but did not agree on how the public could best be induced to demand and make use of the protection Industry spokesmen, for example, said the wisest course to follow would be a public educational campaign, but they did not think the manufacturers should take the lead in this

Representatives of five big manufacturers—Ford, General Motors, Chrysler, American Motors, and Studebaker-Packard—testified at length on car construction and technicalities of installation of seat belts The Ford spokesman said he was certain that universal use of safety belts would reduce traffic fatalities by 50%, and a representative of the Air Force quoted figures to show that auto accidents caused more injuries to Air Force personnel than any other type of accidents and that only airplane crashes caused more fatalities Col John Stapp of the Air Force aeromedical research laboratory said he personally favored belts and thought they might eventually be required equipment on Air Force ground vehicles

J B Hansen, head of the General Services Administration's motor equipment division, while granting that the value of belts had been demonstrated, said auto riders, unless under orders, 'just won't or don't like to use belts,' and that some of the belts are of inferior quality and dubious reliability

The only witness who flatly opposed the belts was Andrew J White, director of a private motor vehicle research organization If it is possible to select the type of accident you are going to be involved in, wear a seat belt, if not, do not wear one as it may be the cause of death or serious injury"

Mr White argued that the government and the industry should attack the whole problem of passenger safety, not just one facet of it He called for a 'massive plan of action" to bring the entire structure of the cars in line with recognized safety principles"

Little, Brown & Company, 1954, p 23, par 2

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, New York

Washington News—Continued

Dr R Arnold Griswold, representing the American College of Surgeons, directly challenged Mr White's testimony He said the enforcement of adequate standards would correct the problem of faulty or inadequate belts, and he cited statistics that indicated less than 1% of auto deaths are due to drowning or fire, situations where it had been argued the belts actually are a handicap

"It is our opinion,' he testified, "that an occupant protected by a seat belt would more likely be conscious and able to extricate himself from a burning or submerged vehicle than would an unprotected occupant who is likely to be unconscious'

FIRST ASIAN INFLUENZA VACCINE RELEASED FOR USE

Only two and one-half months after pharmaceutical houses were given prototypes of Asian influenza virus and asked to attempt to develop a vaccine, the Public Health Service was able to announce release of the first two lots of the vaccine

The first release totaled 502,000 doses, 320,000 cc from the National Drug Company and 182,000 from the Lederle Laboratories Also at work on the vaccine, and expected to have shipments ready shortly, are Eli Lilly & Company, Merck, Sharp & Dohme, Parke, Davis & Company, and Pitman-Moore Company Their first lots now are under review and test

It is understood that somewhat less than half of this release of vaccine will be turned over to military authorities, the rest being distributed through normal channels to physicians, hospitals, clinics, and other health facilities

The Public Health Service has called in members of the State and Territorial Health Officers Association and other health groups, including the American Medical Association, for a special meeting on Aug 27-28 An earlier meeting, attended by representatives of 13 organizations in the health fields, endorsed an A M A recommendation that local groups in the health professions be formed to handle epidemic problems

PHS ALLOCATES MOST OF FUNDS FOR RESEARCH EXPANSION

The Public Health Service already has allocated $26,500,000 of the 30 million dollars appropriated by Congress for the second year of a three-year program to expand health research facilities The money became available on July 1

In announcing the grants, Surgeon General Burney said, 'It is apparent that this program is meeting a nationwide need for assistance in the construction of health research facilities Funds may be used for building and equipment

The money goes out in 100 grants to 77 institutions, including hospitals, universities, research institutes, and schools of medicine, dentistry, and public health They must match the federal money on a 50 50 basis

Since start of the program on July 1, 1956, a total of 275 formal applications and 81 supplemental requests totaling 114 million dollars have been received, and in addition 83 institutions have indicated their intention to apply for 38 million dollars

The following institutions receive grants of half a million dollars or more out of the new allocations University of California at Los Angeles, $600,000 and $1,200,000, University of Connecticut, $650,000, California State Deparment of Public Health, $600,000, University of Georgia, $631,037, Chicago Medical

School, 1 million dollars, University of Illinois, $750,000, Purdue University, $548,197, Tulane University School of Medicine, $1,500,000, University of Boston School of Medicine, $1 500,000, Harvard University, $1,026,000, University of Michigan, $600,000, Wayne State University, Detroit, $500,000, University of Minnesota, $892,821 Washington University, St Louis, Mo , $743,238, Memorial Center for Cancer and Allied Diseases, New York City, $1,060,000 Western Reserve University and University Hospital, Cleveland, $1,175,286 University of Pennsylvania, $1,200,000 Women's Medical College of Pennsylvania, Philadelphia, $500,000

PHS also has allocated the major portion of money available for this year in another two-year-old program, that for grants to communities to help them build sewage treatment plants A total of almost 38 million dollars has been awarded out of 50 million dollars voted for Congress for the current fiscal year, which started on July 1

To the federal money, communities added almost 129 million dollars, indicating total expenditure of 167 million dollars on the projects The average U S grant was about $85,000, and the average community receiving a grant had a population of 22,300

VA INCREASING FEES UNDER HOME-TOWN CARE PROGRAM

The Veterans Administration is increasing fees to physicians under its home-town care program and has allocated another half-million dollars to meet the additional costs in the present fiscal year The VA estimates that the total program will cost about $8,300,000 in the year ending July 1, 1958

New fee schedules have been worked out with medical societies or intermediary organizations in California, Colorado, Connecticut Indiana, Maine, Massachusetts, New Jersey, Ohio, Oregon, Virginia, and Washington, and new arrangements are under negotiation for Arkansas, Florida, Georgia Idaho, Pennsylvania, South Dakota, Alaska and Hawaii

Catalog 5 charges have been revised upward in the 15 states, the District of Columbia, and Puerto Rico, where the VA has no contracts for home-town physician service Amounts of increases and types of services covered by the fees vary from state to state

NEW RESEARCH PROJECT ON THE AGING

An award of $306,922 for research on aging has been made by the Public Health Service to Duke University at Durham, N C , thus launching, in the words of the PHS, a new research approach to the health problems of older persons The grant came from funds of the National Institute of Mental Health and the National Heart Institute, upon recommendation of the two advisory councils to the institutes

Surgeon General Burney said the program is aimed at encouraging establishment of research centers in which departments of universities along with health and related agencies in the community will cooperate in studying various aspects of aging The PHS program is being directed by the Center for Research on Aging at the National Institutes of Health Organized last October the center is under the direction of Dr G Halsey Hunt

At Duke the award will be used to aid in (1) development of a Center for Aging Research based on a university-wide effort, (2) support of fundamental research concerned with health problems of aging, (3) training investigators interested in problems of aging, and (4) fostering a regional resource for dissemination of scientific knowledge in the field of aging

one glycoside consistently reliable for

- routine or emergency digitalization
- long-term maintenance

with the added benefits of

- **early gastrointestinal warnings of over-digitalization**
- **short duration of toxicity if over-digitalization occurs**

POSTPHLEBITIC SYNDROME

Geza de Takats, M D, Chicago

• *The postphlebitic syndrome in the lower extremity follows thrombosis in the deep veins of the pelvis, thigh, or leg, the symptoms are edema, development of collateral veins, pigmentation, induration, especially above the medial malleolus, a characteristic dermatitis, and ulcer In about half the cases the thrombosis was connected with childbirth, injury, surgery, infectious disease, or prolonged immobilization Recanalization of the thrombus destroys the valves and leads to postural regurgitation Incometent communicating veins freely transmit, from the deep to the superficial veins, the sudden rises of venous pressure during coughing, lifting, straining, and sneezing The symptoms follow in a definite sequence, and the patient may present himself at any stage, from that of the initial thrombosis and subsequent bouts of periphlebitis, through the stages of edema, varicosities, pigmentation, dermatitis, and induration, to that of ulcer In order to prevent the long lasting, recurrent disabilities seen in the later stages, intensive treatment of the earlier stages is necessary*

The postphlebitic syndrome consists of a progressive development of deep venous insufficiency and its complications It is caused by a deep venous thrombosis in the pelvic veins or the deep venous system of the lower extremities This, in turn, produces edema, development of collateral veins, pigmentation, induration at the typical location above the medial malleolus, ulceration, and the so called stasis dermatitis Dermatologists are naturally interested in the large painful ulcerations and the dermatitis surrounding it It is my purpose to discuss my experience with this highly disabling, recurrent condition

Incidence and Prevention

The incidence of postphlebitic syndrome is difficult to estimate While many patients give a clear-cut history of a deep venous thrombosis after childbirth, injury, operations, infectious diseases, or prolonged immobilization, just as many patients have no recollection of such a vascular accident in the veins A "Charley horse' after bowling, an ankle-sprain, or a "ruptured muscle," so diagnosed and so treated by taping, is often the beginning of a series of events leading to serious disability

In the Scandinavian countries, where cases of postphlebitic ulcers are registered and covered by government insurance, the disease is regarded as a major disability causing the state an ever-recurring expense It is said to cost Denmark $291,000 and Sweden $582,000 a year

In the United States it is impossible to hazard a guess of the frequency of the disease, since many patients are not hospitalized and mortality is almost negligible, though invalidism is amazingly high Since the patients are in the hands of general practitioners, dermatologists, surgeons, druggists, soothsayers, and well-meaning neighbors, statistical figures are meaningless In the vascular clinics of medical schools, they constitute an ever-growing mass of disabled and much-suffering people for whom no amount of bed space is ever sufficient

The prevention of this progressive deep venous insufficiency lies, of course, in the early recognition of deep venous thrombosis and its intensive treatment with heparin sodium, elastic compression, and early ambulation Since most of the deep venous thromboses start in the foot and calf, an arrest of thrombosis below popliteal level prevents lasting edema and its sequelae One seldom sees the lesion at this stage and is usually confronted with the full-blown picture of the postphlebitic syndrome, simple to recognize and difficult to treat

Pathophysiology

Recanalization of the deep venous thrombus destroys the valves and leads to deep venous insufficiency, in other words, to postural regurgitation In 1929, my co-workers and I[1] measured venous pressure from the

---

From the Department of Surgery, University of Illinois College of Medicine, and the Presbyterian-St Luke's Hospital

Read at the 15th annual meeting of the American Academy of Dermatology and Syphilology, Chicago Dec 12 1956 right side of the heart to the point of measurement Recently, the dynamics of venous circulation caused by the crippling of valves after thrombosis has been intensively studied in a number of clinics, including the one at the University of Illinois College of Medicine[2] It can be done by venography (fig 1), which we at the University of Illinois College of Medicine have used rather sparingly, by venous pressure measurements before and after exercise (fig 2),[2] and by clinical tests designed to locate the site of incompetent perforators (fig 3)

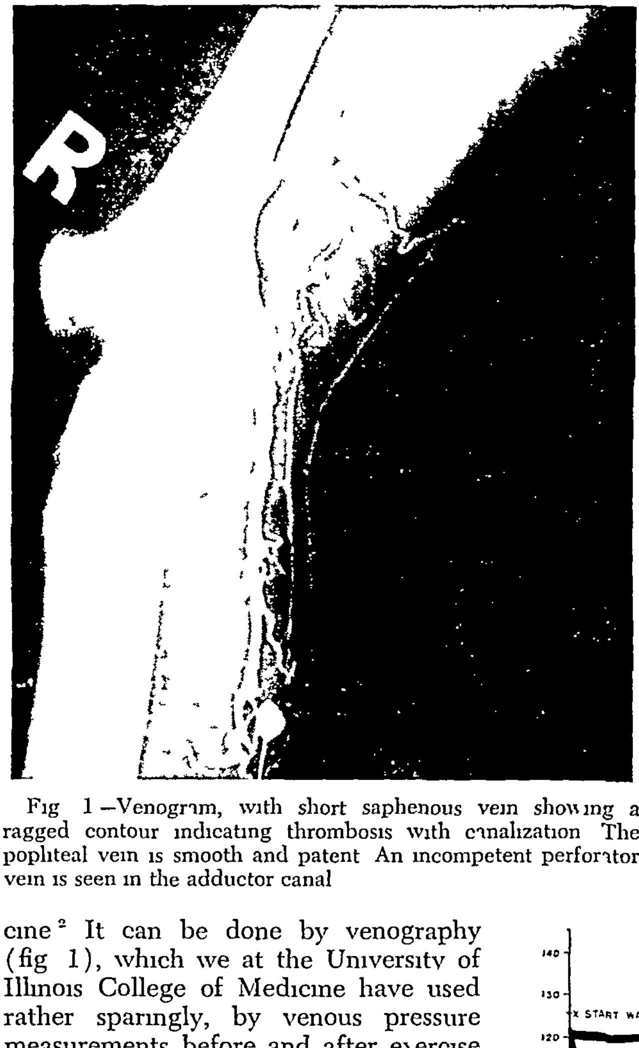

Fig 1—Venogram, with short saphenous vein showing a ragged contour indicating thrombosis with canalization The popliteal vein is smooth and patent An incompetent perforator vein is seen in the adductor canal

In order to obtain the venogram shown in figure 1, 35% iodopyracet (Diodrast) compound was injected into a saccular dilatation of the short saphenous vein, which enters the popliteal vein at the level of the lower margin of the patella Without going into details, one can state that normally the superficial system does not fill from the deep veins, that phlebography often localizes the level of obstruction in the superficial femoral vein in the thigh and shows huge tortuous perforator veins connecting the deep with the superficial venous system On muscular contraction, the opaque material routinely passes from the deep to the superficial venous system, as observed under the fluoroscope[3]

Fell and co-workers[3] showed that, when the communicating veins become incompetent, the sudden rises of venous pressure which occur on coughing, lifting, straining, and sneezing are freely transmitted to the superficial system Thus when the valves are incompetent, as occurs in the postphlebitic syndrome, the venous system functions as a unit (fig 4) and a retrograde transmission of hypertensive waves in the venous system due to effort leads to pain, edema, elongation, and tortuosity of capillaries and venules, thrombosis, and rupture of the cutaneous venocapillary network[4]

Clinical Manifestations

The postphlebitic leg exhibits edema, pigmentation, varicosities, pain, stasis dermatitis, induration, and ulceration in this decreasing order of frequency Bauer[5] has particularly been emphatic about the time element in the development of these sequelae All his patients showed edema in the affected leg from the very start Induration was seen in 45% 5 years after the onset of acute phlebitis, in 72% after 10 years, and in 91% later on Ulceration of the leg was seen in 20% 5 years after the acute phase, 52% after 10 years, and 79% later on

It has been my experience that energetic treatment of the acute phase with heparin sodium, elevation, tight elastic compression, and possibly a mercurial diuretic or acetazolamide (Diamox) may so minimize the edema that the hard, lymph stasis will not supervene In such cases, deep thrombosis will not be followed by these complications It is also possible that a short segmental thrombosis may develop, which is readily compensated by collateral deep veins and which does not recanalize

Induration—The involved extremity is usually but not always larger than the unaffected one, but bilateral involvement is very frequent In one group of cases, edema is absent and there is well-developed collateral circulation This is called compensated venous circulation, and it is significant that skin manifestations subcutaneous indurations, and ulcerations are absent In the majority of cases, however, due to neglected early treatment or to the extent of the occluding venous thrombus, there develops a subcutaneous plaque of

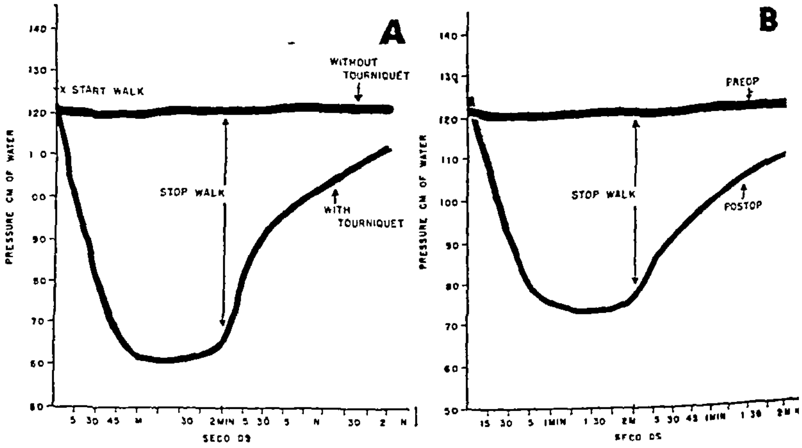

Fig 2—Walking venous pressure pattern of right leg before and after high ligation and stripping of superficial varicose veins A, before operation, venous pressure remained at 122 cm H O while patient both stood and walked With tourniquet, the pressure dropped to one-half of the standing pressure on walking, which is the normal response B, after operation, normal venous hemodynamics restored (Published with permission of Dr Schneewind, of the University of Illinois College of Medicine)

indurated fat and subcutaneous tissue which is hard and often recurrently inflamed It seems to be centered around some perforator veins on the medial aspect of the leg about the width of the hand above the inner malleolus (fig 5) and may start as a small patch to grow proximally and distally This postphlebitic induration may take on huge proportions, it may encircle the entire leg like a tight band or extend as high as the knee, mostly on the medial but sometimes on the lateral and posterior surfaces of the lower leg As John Homans first pointed out, these are areas of lymph stasis, but my dissections during operation have convinced me that the lymphatics are periphlebitic in origin and that invariably there is a canalized or inflamed superficial or communicating vein in the center of the induration

Such indurations may first be painless and show little inflammatory reaction They will flare up, however, on trauma, on infection or reinfection of the toes with fungi, or on a hematogenic basis, as, for example, after a sore throat or a respiratory infection They belong to the group of "delayed reactions to inflammation" and have interesting immunological connotations[6]

Edema—In 1931, Zimmermann and I[7] showed that a protein-rich exudate appears in the interstitial fluid at the production of thrombophlebitic edema This fibrinous exudate acts as a scaffold for the proliferation of fibroblasts and forms a hard, irreversible, nonabsorbable lymphedema The exudate contains growth-promoting properties and also a fibrinolytic ferment which dissolves the fibrin and causes marked retraction of tissue[8] This retraction of tissue is what one sees in an old postphlebitic induration, which retracts so as to give a peculiar inverted bowling-pin appearance to such extremities (fig 6)

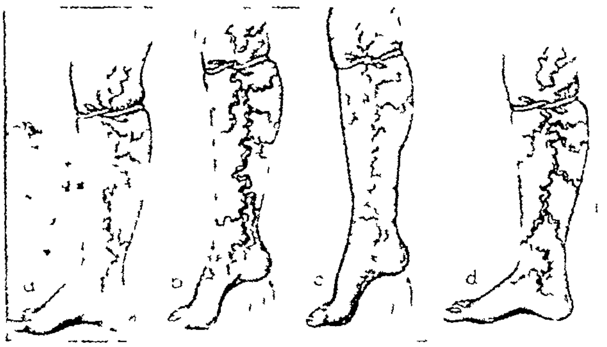

Fig 3—*A* tourniquet placed below knee to obliterate superficial varicosities *B* as patient stands on toes 10 times in 10 seconds visible veins become more distended, indicating increased venous pressure due to deep venous obstruction *C* veins empty on exercise as they should when popliteal vein is patent *D*, veins refill from above in spite of tourniquet being in place, thus indicating deep venous patency but deep valvular incompetence

The obliterative lymphangitis caused by an overload of fibrinous exudate or by superimposed infection reaches the regional lymph nodes, and it is not at all infrequent to encounter their hyperplasia in the popliteal fossa or in the groin Thus, among the many forms of lymphedema which one encounters, postphlebitic lymphedema is frequent and is of mixed, venous and lymphatic, origin As a matter of fact, venous insufficiency improves with time because of the development of collateral circulation, and the residual postphlebitic edema is essentially due to lymph stasis

Stasis Dermatitis—The hard postphlebitic patches are vulnerable, break down easily, and form ulcers, which show poor granulations and are often secondarily infected by a variety of bacteria The skin itself is frequently involved in the form of an acute dermatitis, with or without ulceration, which is usually aggravated by overtreatment and by sensitization and scratching This so-called stasis dermatitis is often followed by a generalized eruption, but there is no question that the edematous leg is the most resistant to treatment

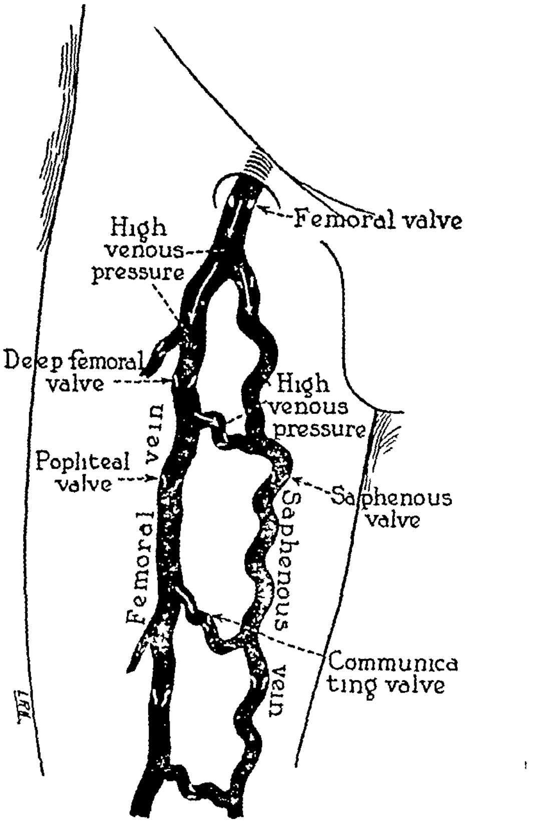

Fig 4—Valvular incompetence in postphlebitic syndrome of saphenous communicating, and deep veins thus causing the venous system to function as a unit (Reproduced with permission from W B Saunders Company)

The mechanism of this stasis dermatitis is beyond my competence to evaluate We do know, however, that extensive venous and lymphatic edema may exist for many years without any involvement of the skin At other times, one has the definite impression that a deep-seated lymphangitis may show a retrograde spread into reticular pattern of lymphatics and that antigen-antibody reactions are always more intense because of the concentration of antibodies in lymphedematous tissue It is sufficiently known that the skin in postphlebitic edema is vulnerable, that incisions and infections heal slowly, that dermatitis resists skillful dermatological care, and that sensitization to sulfonamides, antibiotics, adhesive tape, and petrolatum is very common

The ulcer itself has a poor necrotic base, often producing a periostitis of the tibia, the bacterial flora is variable but contains micrococci (staphylococci), streptococci, Pseudomonas aeruginosa, Proteus organisms, and Escherichia coli[9] The sensitivity of these organisms to various antibiotics can be readily tested, but, as will be pointed out, topical antibiotic treatment is seldom resorted to

The pH of the secretions can be roughly determined by an indicator paper, and it seems that it is mostly acid due to infection and localized ischemia[10] The optimum pH of the granulation tissue ready to accept a graft is above 7 4 Surrounding the ulcers is an induration over which the skin is often thin, atrophic, and loaded with hemosiderin There may also be a second zone of acute inflammatory reaction which may reach from ankle to knee and is very painful

Occasionally one sees a thin strip of itching dermatitis along the course of an inflamed saphenous vein or its perivenous lymphatics I have also seen retrograde spread of periphlebitis originating in fungus infections of the vulva and vagina, these may take on the aspect of an epidemic, as happened in a nursing school in West Virginia Other complications consist of small venocapillary thromboses near the skin surface, petechiae, and an occasional massive hemorrhage from a feeder vein just below the ulcer More frequent are the recurrent thromboses in collateral veins, with much periphlebitic reaction around them, thus causing the physician much alarm and leading to weeks of bed rest, which is unnecessary

Treatment of Various Phases

Incipient Deep Thrombosis—There are, of course, many stages of this progressive development of deep venous insufficiency, and I shall start with the description of the treatment of incipient deep thrombosis In this early phase, there is calf pain, perhaps a little cyanosis on dependency, and possibly some distention of the dorsal veins of the foot as compared with those of the unaffected side There may be minimal or no edema On inflation of a blood pressure cuff on the affected limb to 80 to 100 mm Hg, severe pain is experienced, whereas the normal calf will tolerate pressures up to 180 mm Hg without pain[11] The dorsiflexion of the foot evokes pain in flexor muscles of the calf or in the popliteal fossa, but this sign of J Homans' is only present in roughly one-half of the cases The affected calf, however, is frequently warmer

A patient with such a condition is immediately hospitalized, with the foot of the bed being elevated 8 to 10 in above the horizontal The leg is snugly wrapped from toes to knee, and heparin is given intravenously, with 100 mg being given every six hours for three days, followed by 100 mg given subcutaneously every eight hours for two weeks The patient is ambulatory after three days and frequently may go home on the fifth day, administering the subcutaneous injections to himself for two weeks He then wears an elastic hose for 6 to 10 weeks, depending on the amount of swelling[12]

This early treatment eliminates or minimizes the postphlebitic syndrome, but, unfortunately, most patients are not seen so early or they are immobilized for weeks in bed, with such immobilization favoring an ascent of the small thrombus in the calf to the femoral or iliac segment When the thrombus reaches the popliteal level, sudden, painful, massive edema develops in the calf When it reaches the iliofemoral segment, the entire extremity enlarges and becomes cyanotic and cold with diminished pulses, thus exhibiting the symptoms of reflex vasospasm and sweating In this stage, one can aspirate the femoral thrombus with the patient under local anesthesia, suture or ligate the femoral vein, and start regional heparinization by having 100 mg of heparin in 5% dextrose solution drip into a superficial vein at the ankle two to three times a day In case of vasospasm, the lumbar sympathetics are blocked with procaine hydrochloride, but this should always be done before, not after, heparinization, because massive retroperitoneal hemorrhage or fatality may occur

All this is done to minimize residual edema, since this early soft edema may still be mobilized Later the edema becomes mixed, mostly lymphatic, develops hard patches with subcutaneous fibrosis and fat necrosis, and will require surgical removal

Periphlebitis—The treatment of the fully developed postphlebitic syndrome needs considerable individual variation Recurrent bouts of periphlebitis are treated by short intervals of intense elevation of the limb Phlebitis and periphlebitis in the collateral veins require no prolonged bed rest, but small doses of x-ray not exceeding 80 r, with a heavy filter being used, have been shown by my co-workers and me[13] to be useful The definitive treatment of these recurrent phlebitic bouts consists of a thorough removal of all superficial veins with ligation of the incompetent perforators after the acute attack has subsided

Edema—The control of the edema is important A large edema of the thigh prohibits elastic compression reaching only to the knee, individually fitted elastic stockings are fairly satisfactory, but postural drainage of the edematous limb should be done overnight by having the foot of the bed raised as well as having it raised two or three times during the day for 30 minute periods Certainly if the leg is only swollen to the knee, a well-applied elastic bandage made of crepe or of rubber is very effective A hose can be worn in the evening for improvement of the appearance of the elastic support, but it is seldom as efficient The hose or any impermeable material is contraindicated, however, in case of a dermatitis, since sweating under the hose aggravates the skin lesion

Most patients discover that motionless standing, sitting with the feet hanging down, excessive intake of alcohol or any other liquid, too much salt in the diet, and the premenstrual state with sodium retention aggravate the edema For this reason, all these factors should be avoided or minimized as much as possible An antidiuretic, such as ninhydrin or acetazolamide, given orally for four to five days before menstruation seems to depress the water retention

Varicosities—The huge varicosities of the long or short saphenous vein, which in the past were regarded as a compensatory collateral circulation, are now regarded as being due to a valvular insufficiency resulting from recanalized thrombi and unquestionably contribute to the insufficient venous return, to the poor arterialization of the tissues, and to the terminal venocapillary stasis and thrombosis For this reason, these are thoroughly ligated and stripped, with special attention to the incompetent perforators[14] One has to postpone this procedure, however, if there is an acute dermatitis present or if there is an acutely inflamed postphlebitic ulcer

Dermatitis—The acute dermatitis is managed with the help and advice of the dermatologists, with whom we at the University of Illinois College of Medicine have had very close teamwork The use of wet dressings with weak solutions of aluminum subacetate applied for one hour three times a day and alternated with a 3% iodochlorhydroxyquin (Vioform) ointment in water soluble base has been very useful More recently the use of steroid ointments, notably 1 and 3% hydrocortisone (Hydrocortone), with and without an antibiotic combination, has been useful I am not impressed with the oral use of cortisone and its homologues and feel it has been abused by the general practitioner and some of the specialists Since extensive surgery may have to be done in many of these patients, the danger of a postoperative adrenal insufficiency is a real hazard and may require massive postoperative doses of cortisone and a slow withdrawal of the drug It also causes fluid retention and the type of hypochloremic alkalosis which one sees in certain types of hypertension

Induration—The postphlebitic induration, which usually starts with a small subcutaneous patch of fibrosis and fat necrosis surrounding an incompetent perforator vein, spreads up and down the calf on the medial side and rather infrequently on the lateral or posterior side The induration is first painless and can only be recognized when it is looked for, but later it will involve the skin and give it the orange-peel aspect of breast cancer The induration gradually extends toward the knee or may surround and constrict the ankle, giving it the appearance of an inverted bowling-pin It will get painful, red, and hard after an injury or an infection of any sort and must be treated either with hot fomentations and bed rest or by a semirigid support, such as a glycerin-gelatin cast which we have now used in our clinic for over 30 years One can use small doses of x-ray (60 to 80 r with a heavy filter) through this cast and can renew the cast every three to four weeks Ultimately, excision of the induration is best, with the skin being saved unless it is badly damaged, as well as excision of the indurated subcutaneous tissue, the necrotic fat, and even the deep fascia if it is visibly involved

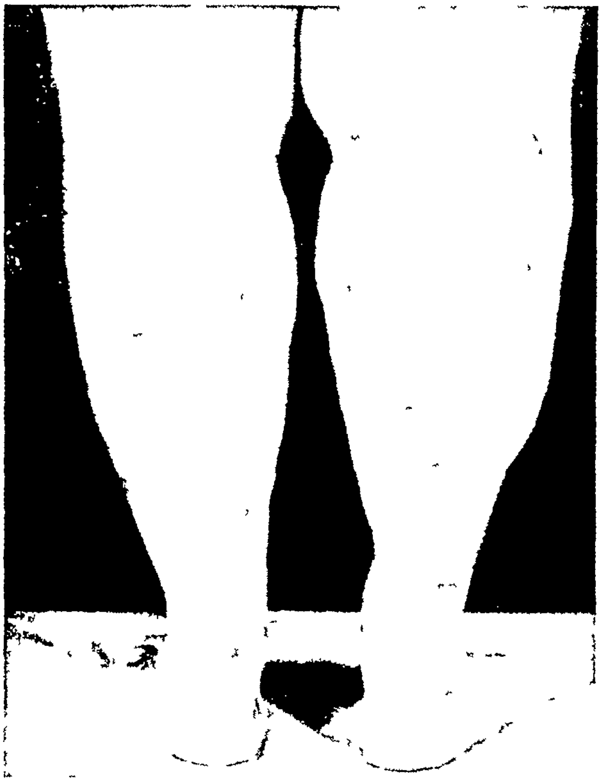

Fig 6—Marked retraction of fibrous tissue above both malleoli of right leg giving leg the appearance of an inverted bowling pin Ligation and stripping of long and short saphenous veins had been combined with excision and split-thickness skin graft

Ulcer—In case the induration breaks down and postphlebitic ulcer (fig 7) develops, several modes of treatment are available One can try to heal the ulcer first with the glycerin-gelatin casts, with the patient kept ambulatory and at work After the ulcer is healed, one can then treat it as a postphlebitic induration by excision, with or without grafting The ulcer with the surrounding fibrous collar can be excised and then 7 to 10 days later a split-thickness skin graft done Or the ulcer can be widely excised and immediately covered with skin, this latter being our choice at the clinic Naturally if the long or short saphenous veins are incompetent, these are stripped at the same time

The most important decision here is whether or not the skin covering the induration should be saved or whether it should be widely excised as in the presence of an ulcer Various methods have been proposed, such as that of using the histamine-flare[9] or a sky-blue dye intradermally[15] to delineate the area devoid of lymphatic circulation In my experience, the palpation of the skin, its texture, atrophy, and obvious vulnerability are the best guides

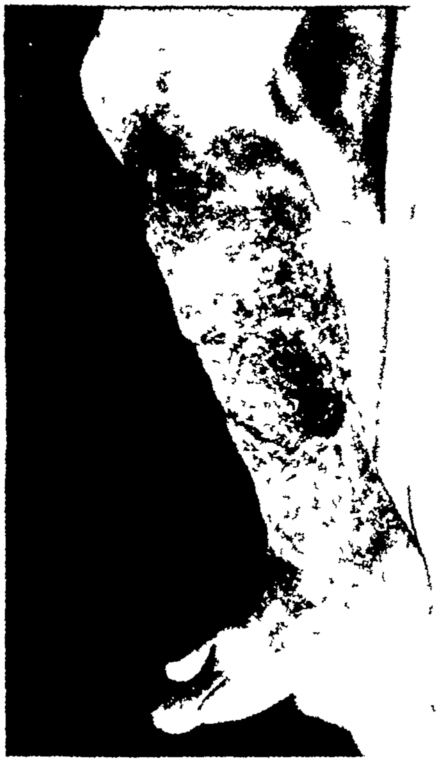

Fig 7—Badly neglected postphlebitic ulcer, with huge induration, dermatitis, and periphlebitic streak at the knee Such a lesion requires patient to be hospitalized four to six weeks

The fate of skin grafts is interesting Most of them have held up under severe strain for 15 to 20 years In 10% of over 200 grafts, the skin broke down again and had to be regrafted in part The causes of the breakdown were direct trauma, insufficient removal of venous back pressure, uncontrolled edema because of poor elastic support, or superimposed arterial disease with or without diabetes Certainly patients with sizable skin grafts should never be without elastic support during the day They should change occupation if possible Bartenders, butchers, motormen on streetcars, and saleswomen are especially endangered Grandmothers holding their grandchildren on their lap have their ulcers reopened by having the grandchildren kick their swollen leg which dates to the birth of the child's mother

Other Methods of Treatment

Some other methods used occasionally for the treatment of the postphlebitic syndrome need to be mentioned Following Bauer's report,[5] Graupner and I[16] ligated the popliteal vein in a small group of patients in whom back pressure through the deep venous system was especially marked Since that report made five years ago, we have ligated a few more popliteal veins but never the superficial femoral vein as originally advocated by Linton and Hardy[17] More recently we have abandoned all deep venous ligations for post-thrombotic sequelae While it is true that the hydrostatic mechanisms are aided by deep venous ligations, during walking or exercise the venous pressures are not relieved but increased[18]

Sympathectomy or repeated sympathetic blocks have been advocated to overcome the vasospastic element in postphlebitic edema We at the clinic have used this method very sparingly and only recognize two indications for it When the postphlebitic leg is cold and clammy and shows diffuse vascular pain, the use of repeated blocks or sympathectomy is most helpful When the postphlebitic leg shows a reflex hyperhydrosis and a recurrent weeping eczema, sympathectomy dries the skin and helps the healing of the resistant eczema In the majority of cases, however, I have not eliminated vasomotor control, since it does not relieve edema in this situation but may even increase it

The chronic postphlebitic ulcer, which is intermittently treated by elastic support, powders, salves, cortisone, and x-ray, may heal and open year after year The saphenous and posterior tibial nerves may become caught in the scar and produce severe pain Through the ulcer, which may take in half of the medial aspect of the calf (fig 7), the patient loses much protein, thus leading to hypoproteinemia He loses sleep, is unable to eat, and is anemic, depleted, and fretful Occasionally the ulcer may show malignant degeneration, and fre-

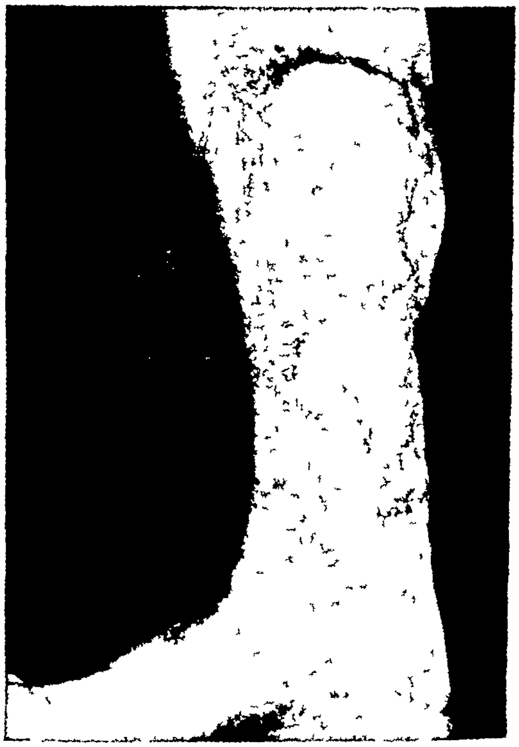

Fig 8—Skin graft in place for seven years in obese cook of low-grade intelligence She had had recurring ulcerations with dermatitis and generalized skin eruptions for over 20 years after a postpartum thrombosis of the right lower extremity

quently an arteriolar sclerosis develops in the surrounding fibrous collar, which prevents the formation of normal granulations and the penetration of antibiotics through the systemic circulation

Many of these patients on coming to the surgeon are sensitized to antibiotics, have had generalized dermatitis, and may have had too much x-ray therapy This can all be avoided by an early surgical excision of the postphlebitic induration and a scrupulous control of any residual edema (fig 8)

Summary

The progressive development of the sequelae of deep venous thrombosis consists of edema, varicosities, pigmentation, dermatitis, induration, and ulceration While many patients do not give a clear-cut history of deep venous thrombosis, it should be suspected in all of those who exhibit varicosities The prevention of this long-lasting and recurring disability lies in early and intensive treatment of the venous thromboses For later stages, the control of edema by elastic support, the elimination of venous back pressure by the ligation and stripping of superficial and perforator veins, the early excision of postphlebitic indurations, and the wide excision and grafting of chronic spreading ulcerations are necessary

Acute Viral Hepatitis—The hepatotrophic viruses responsible for infective hepatitis and serum hepatitis have still not been adequately identified or cultured, neither has a susceptible experimental animal been discovered The time during which the virus is present in the blood and, in the case of infective hepatitis, in the faeces is therefore uncertain It is probably wise to isolate the patient for the first week of jaundice and to take special care in disposal of excreta In view of possible persistence of virus in the blood, convalescents should be banned from ever donating blood There is no safe way of sterilizing human blood or plasma of the hepatitis virus and instances of hepatitis have occurred in recipients of blood previously treated with ultra-violet irradiation or to which *B*-propiolactone has been added Transmission of virus hepatitis by imperfectly sterilized syringes or needles is prevented by dry heat sterilization to 180 C (356 F) for one hour or by boiling for five minutes It is usually recommended that the patient with acute hepatitis should be kept in bed until symptom free, clear of jaundice and until the liver edge is no longer tender Alcohol abstinence should be urged for at least six months, and preferably for one year, after recovery from virus hepatitis Cortisone and corticotropin result in a rapid fall and a lower peak in the serum-bilirubin concentration with more rapid reversion to normal of the thymol and cephalin cholesterol tests These drugs must be continued well into the convalescent stage, because premature withdrawal leads to relapse Prolonged administration of these hormones carries the usual complications In a disease such as hepatitis which tends towards spontaneous recovery, the benefit is not sufficient to justify their routine use They may be considered in the patient who is deeply jaundiced for several weeks, and in relapses—S Sherlock, M D, F R C P, Advances in the Treatment of Diseases of the Liver, *The Practitioner,* October, 1956

ENERGY COST OF THE MASTER TWO-STEP TEST

Amasa B Ford, M D
and
Herman K Hellerstein, M D , Cleveland

• The Master two step test consists of a certain number of trips (approximately 20) over a set of two 9 in (23 cm) steps in 90 seconds The exact number is determined for each subject according to his age and weight, and the score is determined by the time required for the subject's pulse and blood pressure to return to their preexercise levels The calculated total work for the average subject (weighing 77 2 kg) was 710 kg m The work done per minute was 480 kg-m and corresponded to an oxygen consumption rate of 1,485 ml per minute This was found to be about 6 8 times the resting oxygen consumption of all subjects, regardless of age, weight, or health, and to fall between stair-climbing and deep knee bends on a scale of severity for physical exercise Comparisons were made between a group of 12 patients with rheumatic heart disease and 85 volunteer subjects classified as strictly normal The latter were chosen from an initial group of 126 men they had no known history of heart disease, gave normal electrocardiograms during rest and after exercise, had resting blood pressures of 140 mm Hg or less systolic and 90 or less diastolic, and gave normal blood pressure responses to exercise Comparisons were also made between a group of 31 patients with arteriosclerotic heart disease and 40 of the strictly normal subjects matched as to age and weight The strictly normal subjects differed from the cardiac patients in being able to consume oxygen faster during the exercise period The cardiac patients deferred a greater part of the oxygen demand to the recovery period The promptness with which heart rate and blood pressure returned to preexercise levels combined with electrocardiographic changes afforded a better basis for discriminating between normal subjects and cardiac patients than did either the electrocardiogram or the ballistocardiogram alone The Master two step test was found to have a sound physiological basis, especially since the stress it imposes is comparable to the demands of the ordinary activities of life and is constant for patients of different ages and weights

Master's two-step test is widely used as a standardized stress to elicit the electrocardiographic changes of coronary insufficiency Although this form of exercise was originally chosen because of its simplicity and familiarity, there are no data to indicate how severe an exertion it represents or how it can be compared with the stress of ordinary activities of a patient's job The purpose of this study is, first, to measure the energy cost of the two-step test and, second, to observe the physiological reaction to this stress of normal individuals and of patients with heart disease

When Master began to observe the electrocardiographic changes elicited by his two-step test,[1] attention was diverted from its original physiological basis, which did not include the use of electrocardiograms The test consists of approximately 20 trips over a set of two 9-in steps in the period of a minute and a half[2] The exact number of trips is determined for each subject according to his age and weight The number of trips for each category was originally established by determining the maximum number of trips a normal individual of a given age and weight could make and still have pulse rate and systolic and diastolic blood pressures return to within 10 "points" of resting level within two minutes Observations of the recovery rates of pulse and blood pressures were therefore incorporated in the present study, as well as measurements of ventilation, oxygen utilization, oxygen consumption, and oxygen debt necessary to quantitate the energy cost of Master's test In addition, resting ballistocardiograms were taken for correlation with the response to exercise

Subjects

A total of 197 subjects were studied, of whom 126 were in the unselected control group and 71 were in the group of subjects with heart disease

The unselected control group consisted of 126 men, mostly of professional status, who volunteered as "normal" individuals with no known history of heart disease Five of the group were found to have abnormal resting electrocardiograms, and nine, resting hypertension (blood pressure above 140 mm Hg systolic or 90 mm Hg diastolic) These subjects were eliminated as controls, leaving a group of 112 who may be designated "controls normal at rest" Out of this smaller group, 27 subjects showed abnormal response to exercise, 17 in terms of blood pressure and 10 in terms of electrocardiographic changes, as will be defined When these individuals were eliminated, there remained 85 strictly normal controls" who had no evidence of possible cardiac disease by any of the criteria cited There were in the present study 20 such strictly normal controls in each decade from age 20 to 60 years Five subjects in the seventh decade were included who showed abnormal blood pressure response, since it did not appear possible to find subjects of this age without this "abnormality' The 'strictly normal" control group has been used for most of the comparisons in this study, but the 'controls normal at rest" have necessarily been used in evaluating the incidence of abnormal blood pressure and electrocardiographic responses

* From Nomenclature and Criteria for Diagnosis of Diseases of Heart and Blood Vessels [3]

The composition of the group with arteriosclerotic heart disease is summarized in table 1 Ninety-five per cent of the subjects had had myocardial infarction, 63% were placed in class 2 The latter were patients with cardiac disease resulting in slight limitation of physical activity, they are comfortable at rest, ordinary physical activity results in fatigue, palpitation, dyspnea, or anginal pain " [3] The age distribution corresponded roughly to that seen in the clinic population

Nine of the 16 patients in the hypertensive cardiovascular disease group had intermittent or borderline hypertension, and 7 had definite hypertension according to Master s most recent criteria [4] The average systolic blood pressure for the entire hypertensive group was 154 ± 17 6 mm Hg, and the average diastolic pressure was 101 ± 13 6 mm Hg The age range was 31 to 58 years

Six of the 12 subjects with rheumatic heart disease had mitral stenosis and insufficiency, while 6 had combined lesions of the mitral and aortic valves Four were classified 1B, seven, 2C, and one, 3C The ages ranged from 21 to 62 years

Methods

Each subject reported to the laboratory at least two hours after a meal and free of upper respiratory or other infections The step test was demonstrated and practiced once Height and weight were then taken, and a resting longitudinal ballistocardiogram was taken on the Starr table A half-face mask was carefully fitted and taped From the mask, expired air passed through a Plexiglas valve and tubing to a threeway stopcock (minimum internal diameter, 2 0 cm) supported on a light wooden pack frame Expired air was collected in latex weather balloons and analyzed within 15 minutes The total weight of the apparatus carried by the subject was 2 5 kg (5 5 lb) The subject was seated, and his blood pressure was measured at one-minute intervals until a steady state was achieved In this stable resting state a standard 12-lead electrocardiogram was taken, and a five-minute sample of expired air was collected The subject was then instructed to stand and at a signal begin the step test in time with a metronome adjusted so that each subject would complete his required number of trips in one and one-half minutes for a single standard Master two-step test (fig 1) The air expired during the exercise period was collected as a single sample Immediately upon completion of the exercise, the subject was again seated, and a complete 12-lead electrocardiogram was taken Blood pressure and pulse rate were recorded two minutes after completion of the exercise The air expired during the recovery period (13½ minutes) was collected as seven samples, an initial one of 1½ minutes, and the rest of 2 minutes each A second complete electrocardiogram was taken five minutes after the completion of exercise

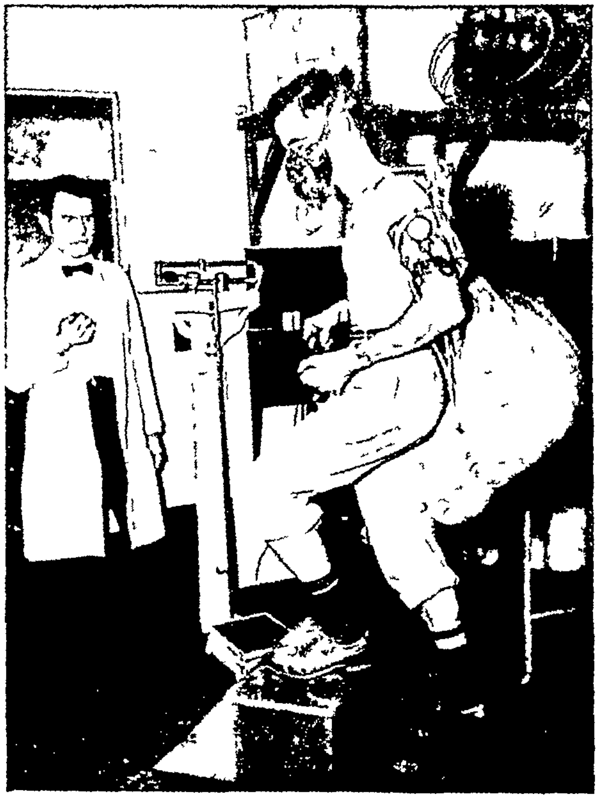

Fig 1 —Subject performing two step test, wearing mask, collecting bag sphygmomanometer and electrocardiographic leads

Expired air samples were analyzed with a Pauling-Beckman oxygen analyzer,[5] and volume was measured with a wet-test gas meter Oxygen consumption was calculated from the following formula

$$OC = V \times 10(O_i - O_e)$$

where

OC = oxygen consumption (milliliters per minute)

V = minute volume of expired air (liters per minute) corrected to standard conditions (760 mm Hg barometric pressure and 0 degree [C] temperature)

O_i = percentage of oxygen in inspired air

O_e = percentage of oxygen in expired air

TABLE 2 —*Response of Eighty-five Normal Control Subjects to the Master Two-Step Test*

	At Rest Mean±S D	During Exercise Mean±S D	During Recovery Mean±S D
Weight kg	77 7 ± 8 6		
Duration of exercise min		1 55±0 095	
Ventilation liters/min	8 09± 1 3	18 9 ±7 5	
Oxygen utilization ml O /100 ml air	3 17± 0 43	5 12±0 65	
Oxygen consumption ml /min	254±37	1 018±120	
Total net* oxygen consumption during exercise ml		1 185±205	
Net oxygen debt ml			1 105±300
Total net oxygen consumption per minute exercise ml /min		1 485±244	
Rate of work kg m /min		480±65	

* ' Net refers to values above resting level

Oxygen utilization is defined as milliliters of oxygen absorbed from each 100 ml of air breathed ($O_i - O_e$) "Work" performed by each subject was taken as the product of his body weight and total vertical distance his body was raised during exercise

Results

Normal Subjects —The response of the 85 strictly selected subjects is summarized in table 2 During exercise the rate of oxygen consumption increased to four times the resting level The cost of exercise was almost equally distributed between the exercise and recovery (oxygen-debt) periods, i e, 1,185 and 1,105 ml of oxygen respectively The increased oxygen consumption during exercise was the product of an increase of ventilation to 2 3 times and of oxygen utilization to 1 6 times the resting levels The various physiological functions (pulse rate, ventilation, oxygen utilization, oxygen consumption, oxygen debt, and work rate) at rest and during exercise were compared by decades to determine whether they were correlated with the age of the subjects The only quantity which showed such a pattern was the rate of work, which was significantly lower (p=<0 01) in each decade above 40 years, as indicated by the *t*-test Since, as has been noted, total net oxygen consumption per minute of exercise was not significantly lower in the older age groups, the ratio of work performed to oxygen consumption was lower in the older subjects This ratio may be considered a rough index of mechanical efficiency It is plotted against age in figure 2 These data suggest that in this brief, moderately severe exercise the older subjects display a slightly lower mechanical efficiency The "strictly normal' control subjects, by definition, showed a return of pulse rate and systolic and diastolic blood pressures to within 10 "points" of resting level within two minutes after exercise The response of the group of controls normal at rest will be considered below

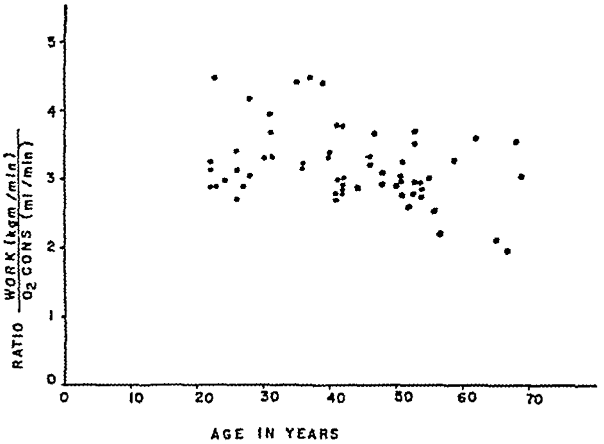

Fig 2 —Ratio of work performed to oxygen consumption (mechanical efficiency) in relation to age of 85 control subjects

* Groups compared by *t* test

† 'Net refers to values above resting level.

Subjects with Arteriosclerotic Heart Disease —Because the control group included more subjects in the third and fourth decades than did the group with arteriosclerotic heart disease, statistical comparison was made in the 40-to-59-year age range, where the groups were comparable in size (40 and 31 subjects respectively) The comparison of the two groups is summarized in table 3 The normal subjects and those with arteriosclerotic heart disease were closely comparable in number, age, weight, and time required to complete the exercise At rest, there were slight but not statistically significant differences in ventilation and oxygen consumption The outstanding and significant difference between the two groups was a diminished ability on the part of the subjects with coronary arteriosclerosis to increase oxygen utilization during this exercise Since they increased ventilation to a level closely similar to that reached by the controls but failed to increase oxygen utilization equally, oxygen consumption during exercise was significantly lower, and the ratio of extra oxygen consumption during exercise to that during recovery (oxygen debt) was significantly lower than in the control group "Mechanical efficiency' (kilograms of work performed to milliliters of oxygen consumed per minute) was slightly lower in the patients with arteriosclerotic heart disease, although the difference is not statistically significant

The response of the entire group with arteriosclerotic heart disease in terms of blood pressure and electrocardiographic changes is presented in table 4 "Abnormal blood pressure response" is defined as failure of either systolic or diastolic blood pressure to return to within 10 mm of resting level by two minutes after exercise [2] "Abnormal electrocardiographic response" is defined by Master [1] and consisted in all cases in this study of an S-T segment depression of greater than 0 5 mm or a primary T-wave change The control group used for comparison here consisted of the 112 controls "normal at rest' An abnormal blood pressure response occurred in a high proportion of patients (65%) but was also observed in the control subjects (17%) Electrocardographic abnormalities appeared in 40% of the patients and 7% of the controls (The electrocardiographic abnormalities in the "normal' adult male sample may be functional [1] or may reflect otherwise inapparent coronary disease) The best discrimination between the two groups is achieved by observing those subjects who show both abnormal responses 4% of the control group and 30% of the arteriosclerotic group

The abnormal response of pulse rate as defined by Master (failure to return to within 10 beats per minute of resting level in two minutes) was not found to be a sensitive criterion It was observed in only three of the patients and one of the control subjects, and these subjects all displayed other abnormalities

Ballistocardiograms For interpretations of the resting longitudinal ballistocardiograms we are indebted to Dr Melvin W Harris, of Canton, Ohio The tracings were read "blind" without any previous knowledge of the subject's diagnosis or response to exercise The criteria of abnormality were those of Dock and coworkers [6] Ballistocardiograms were read as normal, borderline (grades 1 and 2 of Dock's classification), and abnormal Three per cent of the strictly normal group had abnormal ballistocardiograms, and 6% had borderline tracings In the group with arteriosclerotic heart disease, 35% of the ballistocardiograms were abnormal and 27% were borderline Abnormal ballistocardiograms were more frequent in the older age group The average age of control subjects with abnormal records was 54 years (the youngest was 48), while the average age of control subjects with normal ballistocardiograms was 39 years This age difference was not evident in the group with arteriosclerotic heart disease, probably because the average age of the group was greater than that of the control group (49 years vs 40 years)

The data were examined to determine whether an abnormal resting ballistocardiogram in a patient with coronary disease could be correlated with abnormal physiological function during exercise No such correlation could be demonstrated It should be noted that the ballistocardiograms were taken at rest, and the physiological functions were studied before, during, and after exercise It may be that ballistocardiograms recorded after exercise would correlate better Among 12 patients with arteriosclerotic heart disease and abnormal ballistocardiograms, the incidence of abnormal response of blood pressure was 58% of abnormal electrocardiographic response 25%, and of both abnormal responses 17% Among 12 patients of the same age with arteriosclerotic heart disease and normal ballistocardiograms the respective incidences were 42%, 25%, and 17% These two groups were also compared in respect to the physiological functions which had been shown to differentiate the control subjects from those with arteriosclerotic heart disease For those with arteriosclerotic heart disease and abnormal ballistocardiograms, the mean oxygen utilization during exercise was 4 29 ml of oxygen per 100 ml of air, the mean net oxygen consumption during exercise was 870 ml, and the mean ratio of oxygen consumption during exercise to oxygen debt was 0 80 For the patients with normal ballistocardiograms, the respective values were 4 43 ml of oxygen per 100 ml of air, 847 ml, and 0 73 None of the differences are statistically significant (p=>0 5) Similarly, the control subjects with abnormal ballistocardiograms could not be shown to differ significantly from those with normal records except in respect to age

TABLE 4—*Incidence of Abnormal Responses to Exercise of Controls and Three Groups with Heart Disease in Terms of Blood Pressure and Electrocardiographic Changes*

	Abnormal Blood Pressure Response		Abnormal ECG Response		Either or Both Abnormal Responses		Both Abnormal Responses	
	No	%	No	%	No	%	No	%
Controls normal at rest (112)	19	17	8	7	23	21	4	4
Patients with arteriosclerotic heart disease (43)	28	65	1	40	32	74	13	30
Patients with hypertensive cardiovascular disease (16)	9	56	5	31	11	69	3	19
Patients with rheumatic heart disease (12)	6	50	4	33	7	58	3	25

Although no definite correlation is demonstrated between abnormal physiological function and an abnormal ballistocardiogram in the present study, the possibility is not excluded that an abnormal tracing in an otherwise normal individual may indicate occult cardiac dysfunction, especially in an individual under the age of 50 years The ballistocardiogram is demonstrated to have some value as a screening procedure Abnormal ballistocardiograms were present in 35% of the group with arteriosclerotic heart disease Of the group with arteriosclerotic heart disease, 77% had abnormal resting electrocardiograms, 65% had abnormal response of blood pressure to exercise, and 40% had abnormal electrocardiographic response to exercise

Subjects with Hypertension.—The 16 subjects with hypertension were compared with the strictly normal control group, and no striking differences in the previously listed physiological functions were observed. This is not surprising, since these patients had relatively mild hypertension. Oxygen utilization increased less during exercise in the hypertensive group (1.54±0.50 ml. of oxygen per 100 ml. of air) than in the controls (1.92±0.53 ml. of oxygen per 100 ml. of air). The difference is of borderline significance (p=<0.01). Because of slightly higher ventilation both at rest and during exercise, however, there was no significant difference in oxygen consumption at rest or during exercise. As might be expected, there was a high percentage of abnormal blood pressure responses in this group (56%), as shown in table 4.

Subjects with Rheumatic Heart Disease.—The 12 subjects with rheumatic heart disease showed the same physiological abnormality which was noted in those with arteriosclerotic heart disease. Oxygen utilization and oxygen consumption during exercise were less, and oxygen consumption during exercise was less in relation to oxygen debt, than in the strictly normal control group. These differences were all significant (p=<0.001). The data are presented in table 5. None of the other physiological values differed significantly from those of the control group. Abnormal blood pressure responses and electrocardiographic changes occurred about as frequently as in the patients with arteriosclerotic heart disease (table 4).

Comment

The standard Master two-step test has been used, under careful medical supervision, for the evaluation of exercise tolerance in 1,150 patients with known heart disease, of whom 650 had arteriosclerotic heart disease, during the past six years at the Work Classification Clinic of the Cleveland Area Heart Society. The test has not been used in the presence of symptoms or electrocardiographic evidence of a changing myocardial process during the preceding two months. Patients have been instructed to stop the exercise if chest discomfort develops. No adverse reactions have occurred. In our experience the test has been highly informative as to the limits of exertion suitable for a given patient.

The sound physiological basis of the two-step test is demonstrated by the fact that the prescribed number of trips calls for a total energy expenditure equivalent to 6.8 times resting oxygen consumption and that this energy expenditure does not vary significantly with age, weight, or disease state. This brief, moderately severe exercise is performed with approximately equal 'mechanical efficiency' by normal controls and patients with heart disease, but a decline in 'mechanical efficiency' is observed in the older subjects.

This study shows that in the response to this exercise there may be significant changes in physiological function, as well as in the electrocardiogram, distinguishing the normal from the abnormal. The most significant changes are a delayed return of blood pressure to resting levels and a shift of oxygen consumption, such that the majority occurs in the recovery period rather than during exercise. In general, the patient with heart disease displays a lag in the mobilization of metabolic reserves.[7] The failure to increase oxygen utilization normally during exercise must be due either to insufficient cardiac output or to a smaller arteriovenous oxygen difference. Pulmonary factors are not considered here because none of the patients had significant pulmonary disease and none had congestive cardiac failure. There is reason to believe that limited cardiac output is primarily responsible, since the lowest average value for oxygen utilization during exercise (3.87 ml. of oxygen per 100 ml. of air) was observed in six patients with mitral stenosis, in whom a mechanical obstruction to flow is known to be present. If, therefore, the assumption is made that failure to increase the cardiac output normally is at fault, then, since a high pulse rate is characteristic of patients with heart disease during exercise,[7] the patients must have a limited stroke volume, either because of myocardial weakness or because of mechanical obstruction to blood flow. If this is the case, then, in order to supply the requisite total amount of oxygen to the exercising muscles, the cardiac output must remain elevated longer during the recovery period—a factor possibly contributing to the delayed return of blood pressure to resting levels. Another aspect of this delayed metabolic adaptation is the previously demonstrated tendency of patients with heart disease to have higher pulse rates during exercise and to return to resting pulse rates less rapidly than normal.[8] This last feature was not observed in the present study because pulse rate was not measured during exercise and because the single observation of pulse rate two minutes after exercise, prescribed by Master, misses the significant early decline. These various abnormalities in rate of change of physiological function are particularly well brought out by a relatively brief, vigorous exercise, such as the two-step test, whereas they may escape notice in the more usual type of 'steady-state' exercise study in which the initial and postexercise adjustment phases are excluded.

The current use of the two-step test solely for diagnosis of coronary artery disease is not supported by the present study. Neither abnormal electrocardiographic changes nor abnormal physiological responses (delayed fall of blood pressure after exercise and low ratio of oxygen consumption during exercise to oxygen debt) are specific for coronary artery disease, since they occur with almost equal frequency in patients with hypertensive cardiovascular disease, in those with rheumatic heart disease, and, to a lesser extent, in otherwise normal subjects. On the other hand, the test, regarded as a measured stress, is a potential source of more clinical information than is at present recognized It is probable that the abnormal electrocardiographic changes are related to relative coronary insufficiency, whether due to coronary arteriosclerosis, disproportion of hypertrophied muscle to coronary bed, or mechanical factors, such as aortic insufficiency The physiological changes are probably related to myocardial weakness and insufficient cardiac output The clinician can readily take advantage of this additional information by the simple procedure of taking blood pressures before and two minutes after the usual step test In addition, a more detailed observation of the postexercise pulse rate than that originally used by Master would probably give further information This can be obtained easily by taking a continuous electrocardiogram for two minutes after exercise The exact significance of the early pulse-rate changes after this exercise requires further investigation Studies of the proportion of oxygen consumption during exercise to that during recovery would also be useful, although not so readily available as pulse rate and blood pressure These observations give a more complete picture of an individual patient's reaction to the stress of the step test

We return, then, to the original question How severe an exertion does the step test represent, and how does it compare with a patient's ordinary activities? Table 6 summarizes measurements made by us and by other investigators In this laboratory, the step test has been specifically compared with climbing and descending standard stairs at a rate vertically of 20 ft per minute (two flights per minute) The energy cost of these two activities is the same except for minor differences which may be attributed to more frequent turning involved in the step test The step test is moderately severe exercise, demanding 45% of the mean maximal oxygen intake determined by Taylor and associates [9] for young men and 38% of the highest measured oxygen consumption [10] It is, of course, a brief exertion in which a steady state is not achieved It may be compared, as the table shows, with push-ups or with deep knee bends It calls for a rate of energy expenditure much greater than the average sustained rate required by certain representative industrial jobs which require moderate exertion [11] and significantly greater than the maximum spurts of exertion involved in these jobs With this perspective on the degree of stress represented by the step test, plus observation of the patient's response to the test in terms of blood pressure, pulse rate, and electrocardiographic changes, the physician has at hand a rational means of judging an individual patient's fitness for various activities Studies are in progress which will give a more complete description of the energy requirements of a range of occupations, so that the significance of a patient's response to measured stress will be further enlarged

Summary and Conclusions

The energy cost of the Master two-step test has been measured in 71 patients with heart disease and a group of 126 control subjects The test calls for a net rate of energy expenditure of 1,485± 244 ml of oxygen per minute of exercise, or 6 8 times resting oxygen consumption (8 5 calories per minute) This is a rate of energy expenditure equal to ordinary activities, such as stair climbing, and greater than the peak requirements of certain industrial jobs, such as tool grinding Patients with arteriosclerotic heart disease and rheumatic heart disease show, on the average, a failure to increase oxygen utilization to normal levels during this exercise, resulting in a lower oxygen consumption during exercise and the deferring of a greater part of the cost of exercise to the recovery period Clinically, a better discrimination betwen normal subjects and patients with heart disease may be achieved by observing the rate of recovery of blood pressure and, probably, pulse rate than by relying on electrocardiographic changes alone Abnormal ballistocardiograms taken at rest are more frequent in otherwise normal subjects above the age of 50 and in patients with arteriosclerotic heart disease, but they do not appear to be related to abnormal physiological response to exercise

** Cost includes exercise and recovery other figures are for steady state

The Master two-step test is demonstrated to have a sound physiological basis and to impose an equal energy demand in patients of different age and weight The standard test may be safely used under careful supervision in patients with known heart disease who are in stable condition More complete observation of a patient's physiological response to this measured stress should provide a sound basis for counseling in regard to work and the ordinary activities of life

IMMUNIZATION OF COLLEGE STUDENTS AGAINST DIPHTHERIA

Ruth E Boynton, M D, Donald W Cowan, M D
and
Paul Rupprecht, M A, Minneapolis

• *In order to determine the extent of local and general reactions after immunization to tetanus and diphtheria, 2,974 university students were reexamined 48 hours after the first dose The tetanus toxoid (alum precipitated) was given in doses of 0 5 cc intramuscularly to those students who had reacted negatively in the Shick test, those who had reacted positively to the Shick test received intramuscularly 0 5 cc of alum precipitated combined diphtheria and tetanus toxoid Both local and general reactions were more frequent in women than in men For the group as a whole, 70 4% of those receiving tetanus toxoid were found to have local reactions as compared with 51 7% of those receiving the combined tetanus diphtheria toxoid, general reactions, however, were significantly more frequent after the combined tetanus diphtheria toxoid than after the tetanus toxoid The reactions are not severe enough to militate against the routine use of these vaccines in students entering college*

Numerous surveys showing the high susceptibility of adults to diphtheria[1] and the increasing incidence of cases of diphtheria among these older persons[2] have stimulated interest in finding a method of immunizing adults against diphtheria without producing severe local or constitutional reactions Pappenheimer and co-workers[3] as well as others have shown that such reactions may be reduced by Schick testing and immunizing only the Schick-positive group For a mass community immunization program, however, preliminary Schick testing is cumbersome and practically impossible to carry out

During recent years much research has been done[4] to determine the smallest dose of diphtheria toxoid which will produce an antibody response adequate to give protection but without producing severe reactions Some of these studies have shown that as little as 1 Lf dose (the amount of diphtheria toxin which in the shortest time produces precipitation when mixed with 1 standard unit of antitoxin) of diphtheria toxoid, if precipitated or adsorbed, will produce an adequate immune response in most instances without causing reactions Until very recently, however, no diphtheria toxoid of low potency has been available for general use for the immunization of adults While the immunization of adults with the use of standard diphtheria toxoid without preliminary Schick testing is not recommended, adults with a positive Schick test may be immunized with standard diphtheria toxoid with little more chance of severe reaction than that after smallpox vaccination or tetanus immunization[5]

At the University of Minnesota a complete medical examination is required of all new students on admission Since 1935 a Schick test and control test have been included as a part of the examination Those students found to be Schick positive have been advised to be immunized Each year over 90% of the Schick-positive students have accepted the immunization

Since 1935, also, the standard dose of alum-precipitated diphtheria toxoid has been used as the immunizing agent In 1935 the control test used was an intradermal injection of 0 1 cc of a 1 20 dilution of toxoid according to the technique of Moloney and Fraser[6] A report of the experience of one of us (R E B) and a co-worker with the Moloney test in 1935[7] showed that the number of students having local and/or constitutional reactions was higher in those with a positive Moloney test but that this test was by no means specific in selecting students who would have a reaction Since none of the reactions to

---

From the University Health Service, University of Minnesota alum-precipitated diphtheria toxoid in that year were of such severity as to cause any concern, beginning in 1936 heated toxin has been used as the control for the Schick test and the Moloney test discontinued

In the fall of 1951, immunization against tetanus was included in our program All new students entering the university found to be Schick positive were immunized with two doses of alum-precipitated combined diphtheria and tetanus toxoid Those students with a negative Schick test were given two doses of an alum-precipitated tetanus toxoid It has been our impression since that time that there was little difference between the local or constitutional reactions seen in students receiving tetanus toxoid alone as compared to those receiving the combined diphtheria-tetanus toxoid To determine whether this impression was correct a study was made in the fall of 1954 to determine as accurately as possible the extent of local and constitutional reactions in students after the first dose of either the tetanus toxoid or the combined diphtheria and tetanus toxoid

Fig 1—Form for recording local and constitutional reactions in students receiving alum-precipitated tetanus toxoid and in those receiving alum-precipitated combined diphtheria and tetanus toxoid

Plan of Study

Each student receiving either of the immunizing agents was asked to return to the health service 48 hours later At that time the site of the injection was inspected, the size of any local reaction measured in centimeters, and the degree of swelling noted All measurements were made by two nurses who had been carefully instructed in the procedure to be used At the same time each student was queried by the nurse as to whether he had had any signs of a constitutional reaction, such as chills, fever, or sweating episodes, and whether he had gone to bed because of the symptoms or had missed classes The information obtained from the student was recorded on the form shown in figure 1

Each student who reported to the nurse any kind of constitutional reaction was then seen by one of two physicians His temperature was taken, and a more complete history of the symptoms was obtained Any further examination indicated was done If the physician felt that the student needed therapy for the reaction, he was referred to one of the physicians in the health service dispensary for care

A total of 3,560 students received either the tetanus toxoid or the combined diphtheria-tetanus toxoid Of this number, 2,974, or 83 5%, returned in 48 hours for observation and are included in the study Tetanus toxoid was given to 1,583 of the students and the combined diphtheria-tetanus toxoid to 1,391

Results of Schick Test

A Schick test consisting of an intradermal injection of 0 1 cc of commercially prepared Schick testing material and a control test consisting of the same material which had been heated to inactivate the toxin were given to each student Both tests were read at the end of 72 hours and again at the end of 7 days In a small percentage of cases, either the 72-hour reading or the 7-day reading was missed Seventy-five cases in which the control test was read only at the end of 7 days or in which the Schick test was read only at the end of 72 hours are not included

Of the total group of 2,899 students in whom both the Schick and control tests were read at 72 hours and at 7 days, 47 2% had a positive Schick test and 52 8% a negative Schick test (table 1) No significant sex differences were found except in the age group 20-24 years, where the percentage of positive Schick tests was significantly higher for men than for women

For the group as a whole, the percentage of positive reactors was significantly higher in those students 20 years of age and over than in those under 20 years These studies substantiate other studies which show a high degree of susceptibility in the adult population While we have no information as to how many of these students entering the university had been immunized against diphtheria previously, we do know that in the state of Minnesota, from which the majority of these students come, diphtheria immunization has long been accepted by the public and vigorously promoted by the state health department It is significant, therefore, that 42 3% of the students in the 16-to-17-year age group are susceptible to diphtheria

Immunization

Those students found to have a positive Schick test, regardless of reaction to the control test, were immediately given intramuscularly 0 5 cc of alum-precipitated combined diphtheria and tetanus toxoid Those with a negative Schick test were given intramuscularly 0 5 cc of alum-precipitated tetanus toxoid At the time of the injection each student was given a printed slip asking him to return to the health service at the end of 48 hours

Reactions to Immunizing Agents—Table 2 presents the number and percentage of students by age and sex with local and constitutional reactions to either the tetanus toxoid or the combined diphtheria-tetanus toxoid For the group as a whole, 70 4% of those receiving tetanus toxoid were found to have local reactions, compared to 51 7% of those receiving the combined diphtheria-tetanus toxoid This significant difference was found in both men and women

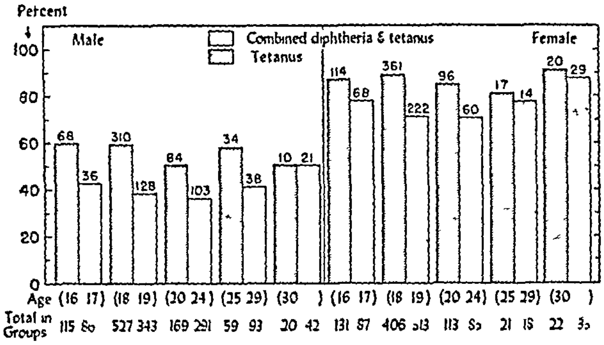

Fig 2—Number and percentage of students by age and sex with local reactions to either combined diphtheria-tetanus toxoid or tetanus toxoid

A significantly lower percentage of men had local reactions to either tetanus toxoid or the combined diphtheria-tetanus toxoid than did women (table 2 and fig 2) In contrast to the higher percentage of local reactions among those receiving the tetanus toxoid, there was a significantly higher percentage of constitutional reactions in those receiving the combined diphtheria-tetanus toxoid As was the case with local reactions, the constitutional reactions were more common in women than in men (table 2 and fig 3)

The percentage of local and constitutional reactions to either the tetanus or the combined diphtheria-tetanus toxoid showed no difference in age groups, with the exception that the number of constitutional reactions to tetanus toxoid was significantly higher in men over 30 years of age than in any of the groups under 30 years Likewise, constitutional reactions to combined diphtheria-tetanus toxoid were significantly more common in men over 25 years of age than in the groups under 25 Figures 2 and 3 show these differences It is difficult to explain why local reactions should be more frequent in women than in men or more frequent in students receiving tetanus toxoid than in those receiving the combined diphtheria tetanus toxoid

Size of Local Reactions—The local reactions after either of the immunizing agents were recorded according to the amount of redness in centimeters at the site of injection and to the amount of swelling present Any reaction in which the maximum and minimum diameters of redness were 3 by 3 cm or less was recorded as one plus, a reaction in which the diameters of redness were 3 by 4 cm or more was recorded as two plus The degree of swelling was recorded as none, one plus (indicating a very slight amount of swelling, either visible or palpable), or two plus (if the swelling was moderate or marked in degree)

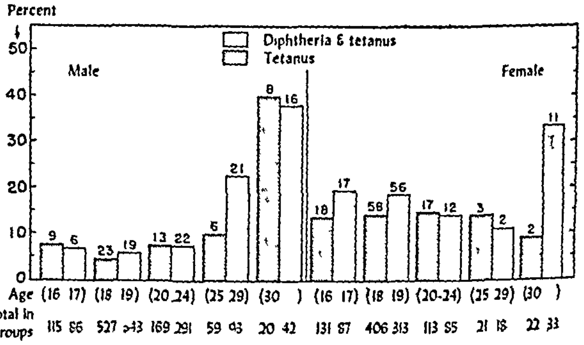

Fig 3—Number and percentage of students by age and sex with constitutional reactions to either combined diphtheria tetanus toxoid or tetanus toxoid

Table 3 presents the local reactions by sex to both antigens by size of reaction and by degree of swelling This again shows consistently not only the higher percentage of local reactions due to tetanus toxoid but also a higher percentage of more severe reactions (two plus) as shown by the size of redness at the site of injection and by the degree of swelling In general, all degrees of local reaction were higher in women than in men, the only exception being in those with two plus swelling

Although the number reporting constitutional reactions of different types show some differences according to the type of immunizing material as well as some age and sex differences, none of these are statistically significant at the 1% level Fewer than 2% of the students receiving tetanus toxoid stated that they had been ill enough to go to bed, and less than 4% of those receiving the diphtheria-tetanus toxoid answered this question affirmatively In answer to the question as to whether they had missed classes, 37, or 2 5%, of the diphtheria-tetanus group stated they had missed classes, while only 16, or 1 0%, of the tetanus group stated they had missed classes This difference, again, is not statistically significant at the 1% level

Constitutional Reactions—Table 4 presents by age and sex the number and percentage of students with certain types of constitutional reactions to both the alum-precipitated tetanus toxoid and the alum-precipitated diphtheria-tetanus toxoid When all types of constitutional reactions are combined, a higher percentage (13 1) of the group receiving diphtheria-tetanus toxoid reported constitutional reactions than did those receiving the tetanus toxoid (9 9%) Although the number reporting constitutional reactions

It is appreciated that these data on constitutional reactions are highly subjective Whether a student missed classes would depend, among other things, on when he had his classes We know that some people will go to bed when feeling slightly indisposed, while others will not However, for the entire group the significantly higher percentage of constitutional reactions in those receiving diphtheria-tetanus toxoid as compared with those receiving tetanus toxoid is probably real

While it is well known that a severe local reaction to these immunizing agents is not necessarily associated with constitutional symptoms, we found a significantly higher percentage of students with more severe local reactions having constitutional reactions after receiving diphtheria-tetanus toxoid Table 5 presents these findings While 5 4% of the total group with no redness at the site of injection reported some constitutional symptoms, 22 6% of those with the greatest area of redness gave a history of constitutional reactions The same relationship is seen in comparing the degree of swelling with constitutional reactions

Table 5—*Relation of Local to Constitutional Reactions in Students Receiving Diphtheria-Tetanus Toxoid*

* + maximum and minimum diameters of area of redness 3 by 3 cm or less ++ diameters 3 by 4 cm or more

† + slight amount either visible or palpable ++ moderate or marked

The relationship between reaction to the Schick control and constitutional reactions following the alum-precipitated diphtheria-tetanus toxoid is presented in table 6 While only 12% of the Schick-positive, control-negative group reported constitutional reactions, one-third of the Schick-positive group who also had a positive control test reported constitutional reactions Although the total number in the Schick-positive, control-positive group is small, this is a statistically significant difference The 206 students in whom the reaction to the control test was unknown are no different from the control-negative group

Comment

It had been our impression that few students have enough discomfort from their toxoid injections to warrant their reporting to our dispensary for advice or treatment, this in spite of the fact that students are urged to and do come in for minor complaints To test the accuracy of this impression, the dispensary records were reviewed for the four-year period beginning July 1, 1951, which was the year we first made tetanus toxoid administration a routine part of our entrance physical examinations

During the four-year period, 24,448 injections of alum-precipitated tetanus toxoid were given, and 48 students reported to the dispensary for advice or treatment of reactions following these injections, an incidence of 1 96 "spontaneous" visits per 1,000 tetanus-toxoid injections Actually this figure is high, since over half of these dispensary visits occurred during the year of the study, which comprises the main body of this report, when the students were asked to return at the end of 48 hours for inspection It is likely that some of those referred to the dispensary by the physician making the inspection would not have come in otherwise

Of these 48 students reporting to the dispensary because of reactions from tetanus toxoid, 5 were hospitalized for a total of six days Five others developed antigenic cysts at the site of injection Comparable figures for alum-precipitated combined diphtheria-tetanus toxoid are as follows 15,421 injections were followed by 46 dispensary visits (2 98 visits per 1,000 injections), 2 patients were hospitalized for one day each, and 2 developed antigenic cysts

It may be added that during this same four-year period, 58 students reported to the dispensary complaining of reaction to smallpox vaccination These were primary reactions and severe accelerated reactions to the vaccine This interested us, because it is often assumed that practically everyone is adequately protected against smallpox before reaching college age Four of these 58 were hospitalized for a total of eight days, including one who had an autoinoculation to the eyelid and was in the hospital 5 days

Summary

Of young adults entering the University of Minnesota in the fall of 1954, 47 2% had a positive Schick test, this in spite of the fact that in this state diphtheria immunization of children has been actively promoted for many years The rate of Schick-positive students was higher for those over 20 years of age than for those under 20 It was also higher for men in the age group 20 to 24 years than for women in the same age group Local reactions occurred in 70 4% of those receiving alum-precipitated tetanus toxoid and in 51 7% of those receiving alum-precipitated combined diphtheria and tetanus toxoid On the other hand, the incidence of general reactions was higher (13 1%) for the combined toxoid than for tetanus toxoid (9 9%)

Table 6—*Relation of Schick Control to Constitutional Reactions in Students Receiving Diphtheria-Tetanus Toxoid*

Sex	Schick Positive Control Negative Group: Total No	Constitutional Reactions: No	%	Schick Positive Control Positive Group: Total No	Constitutional Reactions: No	%	Schick Positive Control Unknown Group: Total No	Constitutional Reactions: No	%
Males	652	55	8 4	33	9	27 3	147	19	12 9
Females	434	75	17 3	30	12	40 0	59	11	18 6
Total	1 086	130	12 0	63	21	33 3	206	30	14 6

Both local and constitutional reactions were more common in women than in men for each of the two vaccines used, and, in general, the local reactions were more severe in women than in men Little age difference was noted in the matter of reactions, except that constitutional symptoms after the administration of tetanus toxoid were more common in men over 30 years of age than in those under 30 and constitutional reactions to combined diphtheria and tetanus toxoid were more common in men over 25 years of age than in men under 25 As would be expected, constitutional symptoms were more apt to occur when the local reaction was more marked, and, in the case of diphtheria-tetanus toxoid, in those who had a positive Schick-control test Only 5 5% of Schick-positive students were also definitely control positive Although some reaction occurs in a high percentage of young adults who receive alum-precipitated tetanus toxoid or alum-precipitated combined diphtheria and tetanus toxoid, these reactions are not severe enough to militate against their routine use in students entering college

MECAMYLAMINE (INVERSINE) IN THE TREATMENT OF HYPERTENSION

John Moyer, M D , Charles Heider, M D
and
Edward Dennis, M D , Houston, Texas

• *The effectiveness of combining reserpine with mecamylamine in treating hypertension was tested in 75 patients, all of whom had sustained blood pressure levels above 150/100 mm Hg before treatment A comparison was made between one group of 17 patients receiving mecamylamine alone and another group of 58 receiving mecamylamine with reserpine The reserpine was given in amounts of 1 mg daily by mouth in four equally divided doses The optimal dosage of mecamylamine was determined by a set dose titration procedure for each patient, beginning with 2 5 mg twice a day the average dose of mecamylamine for those patients who did respond to the drug alone during prolonged treatment was 34 mg daily There were some patients who did not respond satisfactorily to double this dose The data include the average of all blood pressure levels and pulse rates obtained weekly or biweekly for a period of three months approximately one year after beginning therapy with mecamylamine The patient was described as responding to the treatment if it brought about a fall of 20 mm Hg or more in his mean blood pressure or a reduction to the normotensive level, taken as below 150/100 mm Hg The over all response rate for the group receiving mecamylamine alone was 57%, the corresponding figure for the group receiving the combination of drugs was 92% The combination was therefore more effective than the mecamylamine alone The most frequent side effects of prolonged administration of mecamylamine were xerostomia, general weakness, and constipation the most frequent complaints when the combination was taken for many months were impotence, excessive sedation, and blurring of vision*

The most effective therapeutic regimen for reducing blood pressure level in patients with moderate to severe hypertension appears to be the use of ganglionic blocking agents in combination with a rauwolfia alkaloid[1] The concurrent administration of a rauwolfia alkaloid, by depressing the sympathetic nervous system, partially stabilizes the blood pressure response to ganglionic blockade, allows a reduced dosage of the ganglionic blocking agent, and, thereby, decreases the severity and number of the side-reactions Some of the more common side-reactions, such as constipation and postural dizziness, are due to the pharmacological action of these drugs and result most frequently when large doses of the blocking agents are required in order to obtain an effective reduction in the blood pressure level in patients with severe disease Fluctuations in the response of the blood pressure to the ganglionic blocking agents that are currently available occur, in part, as a result of the variability of absorption when these drugs are administered orally Recently, mecamylamine (Inversine) hydrochloride, a long-acting ganglionic blocking agent, has become available for clinical trial[2] It is a secondary amine (rather than a quaternary compound) and is completely absorbed from the gastrointestinal tract Because of this complete absorption, the response after both oral and parenteral administration is essentially the same, in contrast to the response with other ganglionic blocking agents

The results of a preliminary study by us indicated that the administration of mecamylamine in combination with a rauwolfia alkaloid was a very effective

---

From the departments of pharmacology and medicine, Baylor University College of Medicine

Dr Moyer is now Chairman of the Department of Internal Medicine Hahnemann Medical College and Hospital Philadelphia method for reducing the blood pressure level in patients with moderate to severe hypertension and that probably the drug is more effective than a combination of rauwolfia and other ganglionic blocking agents.[2b] These preliminary conclusions were reached after a period of only three to four months of observations. Although over 90% of the patients responded with a significant decrease in their blood pressure levels, it was difficult to evaluate the other beneficial effects of hypotensive therapy, such as symptomatic improvement of headache and angina, after such a brief period of time. Seventy-five patients, however, have now received treatment with mecamylamine alone or in combination with a rauwolfia alkaloid for one to two years or longer, thus, affording us the opportunity to make observations over a longer follow-up period. These observations form the basis of the current report. *An attempt has been made to analyze and* compare the results of immediate and long-term administration of mecamylamine in the treatment of hypertension.

Methods and Materials

The series in this study consisted of a group of 75 patients with moderate to severe hypertension who were treated on an outpatient basis in the hypertensive clinics of the Jefferson Davis (city-county) and Hermann (private) hospitals and included also a number of patients from our private practices, the majority of whom were treated entirely as outpatients. The criterion used for including the patients in this study was a sustained blood pressure level above 150/100 mm Hg during the control period in both the upright and supine positions. Control observations were made by taking the average of a minimum of four separate blood pressure and pulse rate determinations in both the supine and upright positions while the patients received only placebo over a period of three to four weeks. The observations after the administration of the drug are the averages of all blood pressure levels and pulse rates taken weekly in both the upright and supine positions or, in some cases in which the condition was well controlled, biweekly. The therapeutic dose of mecamylamine previously had been established for each patient using the method shown in table 1.

TABLE 1.—*Data Showing Method of Determining Optimal Dose of Mecamylamine*

Week	Dose of Mecamylamine Mg*			
	7 a m	12 Noon	5 p m	10 p m
1st	2.5		2.5	
2nd	5.0		5.0	
3rd	5.0	5.0	5.0	5.0
4th	5.0	10.0	5.0	5.0
5th	5.0	10.0	10.0	5.0
6th	5.0	15.0	10.0	5.0
7th	10.0	15.0	10.0	5.0

* Dose was not increased above that required for adequate blood pressure regulation.

An initial dosage of 5 mg of mecamylamine given orally twice a day (after breakfast and supper) was empirically chosen, but this proved to be excessive in *some cases, resulting in marked orthostatic hypotension* and numerous side-reactions. Subsequently, 2.5 mg twice a day was found to be a more suitable starting dosage. This dosage was then increased by steps until an adequate blood pressure response was obtained using the method of dose determination shown in table 1. In patients who received combined therapy, a standard daily dosage of 1 mg of reserpine in four equally divided doses was given orally in addition to the optimal dose of mecamylamine. The drugs were given after meals in order to allow a more prolonged and constant absorption. The upright blood pressure and symptoms resulting from drug administration were used as a guide to weekly changes in dosage, so as to minimize excessive orthostatic responses and untoward effects. Each patient in the study has been followed for one year or more after beginning therapy with mecamylamine alone or in combination with reserpine. None of the patients received any other antihypertensive drug.

Two post-therapy observation periods are compared. The D_1 period represents the average of all blood pressure levels and pulse rates taken weekly for a period of three months immediately after the initial period of optimal dose determination. The D_4 period represents the average of all blood pressure levels and pulse rates taken weekly or biweekly for a period of three months, approximately one year after beginning therapy with mecamylamine. Dosages of mecamylamine were increased or decreased as deemed necessary throughout the duration of therapy.

For the analysis of data, the 75 patients have been divided into two groups. Group 1 consists of 17 patients who received mecamylamine alone during period D_1, and group 2 consists of 58 patients who received the combination of mecamylamine and reserpine. During period D_4, there were only 14 patients in group 1, whereas there were 61 patients in group 2. The discrepancy in numbers between period D_1 and D_4 for each group of patients is due to the fact that a small number of patients were switched to another group in order to evaluate the effect of reserpine in this drug combination on the same patients. Thus, the administration of reserpine was added to that of mecamylamine after six months of therapy with mecamylamine alone in nine patients. These nine patients, therefore, were in group 1 for period D_1 and in group 2 for period D_4. Eight patients in group 1 received mecamylamine alone during the study. Likewise, in six patients who initially received the combination of reserpine and mecamylamine during period D_1, the administration of reserpine was discontinued after six months, and therapy was continued with mecamylamine alone. Therefore, these six patients were in group 2 during period D_1 and in group 1 during period D_4. Fifty-two patients received both reserpine and mecamylamine throughout the entire study.

Twenty-five additional patients were started on therapy. Eight of these became normotensive while receiving reserpine alone and were omitted from the study series. Five patients died, one from myocardial infarction and four from cerebrovascular accidents, before adequate blood pressure control was obtained, and 12 were dropped from the study series early *either because they moved from the* area and were not followed adequately or because their clinic visits were so erratic that the physician thought it unwise to administer any potent antihypertensive agents.

Prior to starting therapy all patients were carefully evaluated as to previous history and physical examination, complete blood cell count, electrocardiograms, blood urea nitrogen levels, chest roentgenograms, and findings on urinalysis and, in some cases, those on Fishberg concentration tests and phenolsulfonphthalein tests On each return visit, the blood pressure level, pulse rate, weight, and temperature were recorded A brief history was taken, physical examination was made, and side-reactions were noted during both the placebo control period and the period of drug administration The initial laboratory studies were repeated at three-to-four-month intervals A summary of the clinical status of the patients prior to beginning treatment is given in table 2

† Varies from nonspecific T wave changes to left ventricular hypertrophy

‡ Keith Wagener Barker classification percentage calculated on basis of 72 rather than 75 patients

§ Total of patients in subgroups 1A and 2A control upright diastolic blood pressure > 100 mm Hg but < 120 mm Hg

‖ Total of patients in subgroups 1B and 2B control upright diastolic blood pressure > 120 mm Hg

Each of the main treatment groups has been subdivided into subgroups A and B on the basis of the degree of elevation of their upright diastolic blood pressure levels prior to therapy Subgroups A consist of patients in whom the control upright diagnostic blood pressure level was more than 100 mm Hg but less than 120 mm Hg, whereas in subgroups B the control upright diastolic pressure was greater than 120 mm Hg

Of the 75 patients treated, 24 were males and 51 were females There were 22 white and 53 Negro patients The average age of the group was 51 years, with a range of from 28 to 69 years In order to compare the severity of the disease in these patients, the incidence of complications due to hypertension has been recorded in table 2 Subgroups 1A and 2A consisted of 13 patients, and subgroups 1B and 2B consisted of 62 patients In addition to the greater number of patients falling in subgroups 1B and 2B, it is evident that in general the patients in these subgroups had a higher incidence of complications of hypertension than did those in subgroups 1A and 2A In fact, the incidence of complications due to hypertension was high for both groups Renal damage, which varied from proteinuria to fixed specific gravity and an elevated blood urea nitrogen level, was present in 50 (67%) of the patients Varying degrees of cardiac failure were present in about one-third of the patients Twenty per cent suffered from angina, and 57 (76%) of the patients had abnormal electrocardiograms, varying from nonspecific T-wave changes to left ventricular hypertrophy and/or anterolateral myocardial ischemia, the majority having left ventricular hypertrophy Three patients had had previously diagnosed myocardial infarctions shown by the electrocardiograms Nineteen per cent of the patients had had previous cerebral vascular accidents, and one patient had a cerebral vascular accident while being given therapy Seventy of the patients had the retinal changes of hypertensive vascular disease, 25% of these having retinal hemorrhage and/or papilledema

Results

A summary of the blood pressure response to therapy with mecamylamine alone and in combination with reserpine is presented in table 3 Also, the response rate during the initial three months (D_1 period) and one year (D_4 period) after beginning therapy is compared The criterion for responsiveness is a reduction in the mean blood pressure level (diastolic pressure plus one-third of the pulse pressure) of 20 mm Hg or more or a return to normotensive levels (less than 150/100 mm Hg) in the upright position

The results show that the over-all response rate of group 1 (total of subgroups 1A and 1B) was 65% during the D_1 period and 57% during the D_4 period The normotensive response in this group was 41% and 21% respectively The average dose of mecamylamine in the responsive patients in this group was 21 mg daily during the D_1 period and 34 mg daily during the D_4 period, as compared to 37 mg and 62 mg, respectively, for the nonresponsive patients

These results show that there is little difference in the over-all response rate (blood pressure reduction) after treatment with mecamylamine for three months and at the end of one year The average dose necessary to maintain the response, however, increased from 21 mg to 34 mg daily The daily dose was increased nearly twofold in the nonresponsive group without obtaining a satisfactory reduction in blood pressure

Of the patients receiving mecamylamine in combination with reserpine (group 2), 90% of the total group were responsive in the D_1 period and 92% during the D_4 period The normotensive response rate was 34% and 44% respectively Thus, there is no significant difference in the response rate after three months and after one year of therapy The average daily dose of mecamylamine for the responsive patients was 24 mg during period D_1 and 38 mg during the D_4 period, as compared to 16 mg and 44 mg, respectively, for the nonresponsive patients Some of these patients have now been followed for from 18 months to two years There is no evidence of an additional increase in dosage requirement after this period of time as compared to that at the one-year follow-up period

In subgroup 2A, 63% of the patients became responsive during both the D_1 and D_4 periods as compared to 94% and 96%, respectively, in subgroup 2B, made up of the patients who had the more severe disease as judged by the elevated diastolic blood pressure The fact that the response rate was higher in the patients in subgroup 2B suggests that the severity of the disease does not alter the responsiveness of patients to treatment

In every subgroup except subgroup 2A (diastolic pressure less than 120 mm Hg), the average dose of the nonresponsive patients was greater than that of the responsive patients The patients in this subgroup had only mild increases in their blood pressure levels and were very sensitive to mecamylamine Thus, an increase in the dose of mecamylamine, although decreasing the blood pressure to responsive levels during a short trial period, resulted in numerous side-reactions that offset the benefits of therapy obtained at a lower dosage As a result, we regulated the dosage according to symptomatic improvement and side-reactions rather than entirely according to the blood pressure response This does not mean that there was no decrease in blood pressure in these patients but rather that it was not sufficient to classify them as responsive (mean blood pressure reduction greater than 20 mm Hg) without producing episodes of excessive hypotension and occasional syncope

It is quite obvious from comparison of the results in table 3 that therapy with the combination of mecamylamine and reserpine was much more effective in reducing blood pressure than was the use of mecamylamine alone, the response rate of the former being 92% and of the latter, 57% after one year of therapy

Side-effects

A comparison of the side-effects of mecamylamine alone and mecamylamine combined with reserpine is presented in table 4 The major side-effects are qualitatively similar, although there are quantitative differences In general the side-effects of mecamylamine when combined with reserpine are fewer than when mecamylamine is used alone This is especially true after the patients have had therapy for a long period of time, as represented by the patients on combined therapy for a year or longer (period D_4) The incidence of side-reactions during this period is much lower than during the D_1 period, despite the fact that the dosage during the D_4 period was larger than during the D_1 period

The most annoying side-effects of mecamylamine alone and in combination with reserpine were constipation, weakness, and dizziness Constipation was present in 71% of the patients who received mecamylamine alone during the D_1 period as compared to 57% during the D_4 period This compared to 60% and 31%, respectively, in patients who received mecamylamine in combination with reserpine In the majority of these patients the constipation was adequately controlled by cathartics, such as milk of magnesia, cascara sagrada, and mineral oil Weakness was present in 59% and 64% of the patients receiving mecamylamine alone during the D_1 and D_4 periods, respectively, as compared to 46% and 28% in patients who received mecamylamine combined with reserpine In most cases the weakness was not marked and, in fact, was hard to evaluate Dizziness was present at some time during the course of therapy in 41% and 50% of the patients during the D_1 and D_4 periods, respectively, who were receiving mecamylamine alone, as compared to 40% and 28% in patients who received mecamylamine combined with reserpine In most cases the dizziness was due to episodes of excessive orthostatic hypotension Syncope was present on a single occasion in four patients who received mecamylamine in combination with reserpine, and it was probably due to overzealous treatment In general, the dizziness was the most marked on arising in the morning and was usually controlled adequately by decreasing the night dose In some patients, the night and supper doses had to be dropped entirely, and the morning and lunch time doses increased

Sedation, although not annoying to most of the patients, was present in a high percentage of the patients in both treatment groups during both the D_1 and D_4 periods Experimentally, mecamylamine has been

Beneficial Effects

In table 5 there is a comparison of the beneficial effects of treatment of hypertension with mecamylamine alone and in combination with reserpine during a short term of therapy (D_1 period) and during a period after one year (D_4 period) These beneficial effects are improvement either in such subjective symptoms as headache, angina, and shortness of breath or in such objective signs as the electrocardiographic findings and disappearance of signs of heart failure, as well as lessening in the renal damage that existed prior to therapy

It is difficult to reach any definitive conclusions as to the beneficial effects obtained in the patients who received mecamylamine alone because of the relatively small number of patients in this group as compared to the much larger group who received the combination of mecamylamine and rauwolfia Certain trends that persisted throughout the D_4 period, however, were apparent in this group during the D_1 period The outstanding symptomatic improvement in this group was relief of headache and improvement of heart failure

In the larger group who received mecamylamine in combination with reserpine, there was definite improvement in symptoms Seventy per cent of these patients had relief of headache during the D_1 period as compared to 86% during the D_4 period Sixty per cent and 50%, respectively, had relief of angina, while 73% and 77%, respectively, had symptomatic improvement of heart failure About 40% of the patients showed improvement in their electrocardiographic findings during the two treatment periods Forty-eight per cent and 44% of the patients showed improvement of renal function during the D_1 and D_4 periods, respectively

Twenty per cent of the patients showed a reduction in pulse rate of 10 beats or more (bradycrotic response) after receiving mecamylamine alone, as compared to one-half of the patients who received mecamylamine in combination with reserpine This was true in the D_1 period as well as in the D_4 period in both treatment groups The difference in the bradycrotic response in the two groups is probably due to the effect of reserpine therapy on the patients in group 2

When comparing the beneficial effects in the first three months of therapy with those in the period after one year of therapy, it is obvious that there was very little difference in the two periods Apparently, the initial reduction in blood pressure had the most dramatic effect on the symptoms due to hypertensive vascular disease Since there is no difference in the degree of improvement between the two periods, however, it should be emphasized that these patients *maintained their initial improvement and that there* was no progression of symptoms in the group as a whole

Comparison with Other Drugs

There are three types of drugs, classified on the basis of their primary site of action, currently in use for the treatment of hypertension These types are as follows 1 Centrally acting agents to which the rauwolfia extracts belong These agents are usually used alone only in mild cases of hypertension and find their greatest usefulness when used in combination with other drugs 2 Adrenergic blocking agents, such as Dibenzyline (N-phenoxyisopropyl-N-benzyl-β-chloroethylamine hydrochloride), which block vasoconstrictor impulses at the neuroeffector site of the arterioles, resulting in a marked orthostatic blood pressure reduction and a reflex tachycardia, since the sympathetic impulses to the heart are not blocked Likewise once adrenergic blockade is present, there is no response to vasoconstrictor drugs should a severe hypotensive episode occur Hence these agents are limited in their usefulness to special cases in which some degree of adrenergic blockade is desirable 3 Ganglionic blocking agents, such as hexamethonium and pentolinium (An-

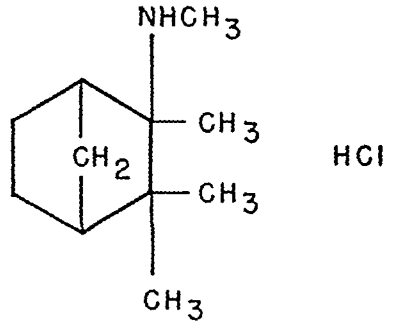
solysen) tartrate, which act by blocking the transmission of impulses through the sympathetic and parasympathetic ganglions

Mecamylamine belongs in the latter group of drugs Unlike the other members of this group (hexamethonium and pentolinium), it is completely absorbed from the gastrointestinal tract, which results in a more prolonged and stable response in the blood pressure reduction The structural formula of mecamylamine is as follows



Results—Table 6 compares the blood pressure response after the long-term administration of mecamylamine in combination with reserpine to that after the administration of hexamethonium, pentolinium, and chlorisondamine (Ecolid) chloride when each of these drugs was used in combination with reserpine The response rate was significantly greater in patients who received mecamylamine in combination with reserpine The optimal dose of pentolinium was 10 times that of mecamylamine, that of chlorisondamine was 7 times that of mecamylamine, and that of hexamethonium was approximately 65 times that of mecamylamine

Side-effects—Table 7 compares the side-effects after therapy for one year or longer with mecamylamine in combination with reserpine to those with hexamethonium, pentolinium, and chlorisondamine when combined with reserpine In general, the incidence of side-effects of mecamylamine used in combination with reserpine was lower than with the other three blocking agents This decrease in the incidence of side-reactions with this drug is probably due to its complete absorption, which diminishes the variability of ganglionic blockade, which exists throughout the day when the drugs are not completely absorbed

The majority of the side-reactions are, of course, the result of both sympathetic and parasympathetic blockade, therefore, are qualitatively similar in all ganglionic blocking agents, and are to be expected when these drugs are used The incidence of these side-reactions, however, can be minimized and the beneficial effects increased by the judicious regulation of dosage, particularly when the drugs are used in combination with centrally acting drugs such as the rauwolfia extracts

Treatment of Side effects

Constipation is one of the most frequent side-effects of mecamylamine therapy If this problem is not combatted vigorously, it may lead to fatal ileus Because of the prolonged action and the potency of this drug, the onset of intestinal paralysis may be more rapid and the severity of the ileus more marked than with any of the other ganglionic blocking agents that are available for oral administration Therefore, it cannot be overemphasized that the therapist must be constantly vigilant for this problem, especially during initiation of therapy, and must treat it vigorously when it occurs Usually, the administration of saline cathartics is adequate, i e, 15 to 30 cc of magnesia magma or 15 to 30 Gm of magnesium sulfate If administration of these is not adequate, irritant cathartics should be tried alone or in combination with the saline cathartics The irritant cathartics that we have found most useful are elixir of cascara sagrada, 10 to 20 cc, or castor oil, 15 to 30 cc Some patients may respond to one cathartic but not to another

† Observation made over a period of 3 months to 1 year only
‡ Average doses in responders were 38 mg of mecamylamine 2 307 mg of hexamethonium 341 mg of pentolinium and 253 mg of chlorisondamine

Cholinergic agents are frequently of value and are often more effective than cathartics We have found 15 to 30 mg of neostigmine (Prostigmine) bromide given orally before each meal to be the most effective cholinergic agent for constipation Five to 10 mg of pilocarpine or 10 mg of bethanechol (Urecholine) chloride given before meals, however, are also effective Pilocarpine appears to be superior to the other cholinergic agents for combating dry mouth, which is frequently observed during mecamylamine therapy

If the constipation has progressed to ileus before adequate therapy is instituted, mecamylamine therapy should be discontinued and 1 mg of neostigmine should be given parenterally every hour until relief is obtained If severe, standard methods for treating ileus should be employed The danger lies in undertreatment of this complication and not in overtreatment Cases 1 and 2 are examples of patients in whom mecamylamine produced intestinal paralysis, which was inadequately treated until marked ileus was present

† Observations on males only
‡ Observations not available

CASE 1—A 48-year-old man was seen with moderately severe hypertension (blood pressure 180/130 mm Hg) but without eyeground changes Therapy with a rauwolfia alkaloid (8 mg of alseroxylon per day) and hydralazine (Apresoline) hydrochloride (800 mg per day) was started He responded well (blood pressure 130/98 mm Hg), but after six weeks he developed a severe reaction to hydralazine (erythema nodosum, fever, joint pains, chills, vomiting, and anuria) After the hydralazine therapy was stopped, the toxic symptoms subsided, but the blood pressure increased to 220/138 mm Hg and he developed precordial pains and retinal hemorrhages Therapy with mecamylamine was started, and the dose was progressively increased so that, after the second week, he was receiving 5 mg four times a day When seen one week later, he complained of severe constipation and abdominal distention A diagnosis of intestinal paralysis was made and the patient was given 1 mg of neostigmine every hour, which was effective after the third dose Recovery was uneventful and the problem of constipation is now easily handled in this patient with the administration of 30 mg of neostigmine before each meal

Another consideration insofar as untoward reactions are concerned is that of aggravating a preexisting renal failure The blood urea nitrogen level seems to be the best method for evaluating any untoward renal effect of blood pressure reduction If the blood urea nitrogen level is above 80 to 100 mg per 100 cc prior to therapy, reducing the blood pressure significantly usually aggravates the renal failure Contrariwise, if the blood urea nitrogen is normal, we have not observed renal failure due to blood pressure reduction unless the pressure was reduced excessively to hypotensive levels (case 2) If the blood urea nitrogen is only moderately elevated (40 to 60 mg per 100 cc), then judicious lowering of the blood pressure with a ganglionic blocking agent, such as mecamylamine, can be undertaken A careful check should be kept on the blood urea nitrogen level as an index of aggravated renal failure, when the effective dose of the blocking agent is reached Usually the blood pressure, taken in the standing position, can be reduced to 160-180/100-110 mm Hg without further compromising renal function in the patient with moderate kidney damage due to hypertension Reducing the blood pressure below these levels must be undertaken with extreme care If the blood pressure can be reduced effectively without significant depression of renal function, progressive anatomic damage due to hypertension will be arrested but not reversed

Case 2—A 50 year-old man with a three-year history of hypertension that had become more severe in the previous six months was seen The patient now had headaches lethargy, confusion, dyspnea, peripheral edema, and retinal hemorrhages His blood pressure was 198/140 mm Hg in the sitting position and 208/148 mm Hg when standing He had retinal hemorrhages and papilledema The electrocardiogram showed severe myocardial damage The blood urea nitrogen level was 30 mg per 100 cc Therapy with a rauwolfia alkaloid was started without a significant effect on the blood pressure It was felt that the patient was completely unreliable insofar as following instructions was concerned, but, because of the severity of his disease it was decided to start mecamylamine therapy The dose, initially 5 mg twice a day, was progressively increased so that, after three weeks, he was receiving 35 mg per day in doses of 5 15 10 and 5 mg Five days later he was admitted to the hospital through the emergency room with a diagnosis of intestinal obstruction He had a distended tender abdomen with periumbilical pain of three days duration When a complete history was taken and the roentgenograms of the abdomen became available, it was decided that the patient had a fecal impaction and ileus due to therapy with the ganglionic blocking agent, mecamylamine The blood pressure was 100/60 mm Hg The blood urea nitrogen level was 58 mg per 100 cc Fluids were administered, and 1 mg of neostigmine (2 cc of a 1 2 000 solution) was given every hour After the fourth dose, an explosive bowel movement occurred The blood pressure increased slowly to 120/80 mm Hg, and convalescence was slow but progressive over the next four days The supine blood pressure level remained normal but the patient could not stand up due to orthostatic hypotension Thereafter this marked orthostatic effect improved, and the patient s blood pressure was regulated by the administration of reserpine plus mecamylamine The subsequent clinical course during three months, was uneventful, and the blood urea nitrogen level again decreased to 28 mg per 100 cc

It is to be emphasized that there is no average daily dose of mecamylamine for any one patient and that the dosage for each patient must be determined individually It is important to start the patient on relatively small doses and to increase the dose slowly in order to avoid excessive hypotension and side-reactions The patient should be seen frequently during the initial period of dose determination, and once the therapeutic dose is established it is not necessary to see the patient quite so often

Comment

The results of this study indicate that mecamylamine in combination with a rauwolfia alkaloid (reserpine) is a very effective method of treatment for moderate to severe hypertension and is more effective than reserpine combined with hexamethonium, chlorisondamine, or pentolinium Also, combined therapy is much more effective than when mecamylamine is used alone We feel, therefore, that mecamylamine in combination with reserpine is the treatment of choice in moderate to severe hypertension Mecamylamine is considerably more potent than other currently available ganglionic blocking agents, and, therefore, the dose should always be titrated carefully in each patient in whom it is used We feel that the starting dosage should be 2 5 mg twice a day, to be increased on following visits according to the response of patient s upright blood pressure level Some patients require small doses to produce the desired blood pressure response In patients requiring larger doses, use of the method of dose determination shown in table 1 is recommended

The initial response to treatment with mecamylamine is maintained after a long period of therapy, and, in addition, the incidence of side-reactions, which are present initially, tends to decrease when therapy is continued The initial symptomatic improvement that is observed after treatment with mecamylamine is maintained when therapy is continued for one year or longer

Severe renal and cardiac disease are not contraindications to therapy, since the response rate in the group of patients with more severe disease was found to be just as high as that in the group with less severe disease The blood urea nitrogen level should be followed carefully as a guide to any progression of renal disease, and sudden drops in blood pressure should be avoided, since this may cause a decrease in renal function The majority of side-reactions can be regulated adequately by proper dosage and by the administration of drugs that offset some of these side-reactions Constipation should be controlled with cathartics The patients should be instructed as to the side-effects to be expected and as to their importance and regulation

Summary

Seventy-five patients with hypertension were treated with mecamylamine (Inversine) hydrochloride alone or in combination with reserpine for one year or longer,

and a comparison was made between the immediate response and the response after one year of treatment The comparison of results with mecamylamine, hexamethonium, chlorisondamine (Ecolid) chloride, and pentolinium (Ansolysen) tartrate indicates that mecamylamine is a much more potent ganglionic blocking agent than the other drugs In addition, the response is less variable due to the complete absorption of this agent Mecamylamine when used in combination with reserpine was found to be more effective than mecamylamine when used alone The side-effects are primarily those of ganglionic blockade, which are present to a less degree with mecamylamine than the other blocking agents and, indeed, are decreased when mecamylamine is used in combination with reserpine

COMMUNITY HEALTH AND WELFARE PLANNING

ROLE OF THE LOCAL MEDICAL SOCIETY AND ITS MEMBERS

Myles MacDonald, M S W
and
LeRoy G Cooper, M D, York, Pa

Practitioners of the healing arts have always been accorded social prestige and have been ascribed abilities and competencies often beyond their actual skills The healing priest, shaman, apothecary, and surgeon have exercised influence over kings, chiefs, and societal leaders by virtue of their health-maintaining functions In North America, during the last century, the doctor in small towns and large cities enjoyed unprecedented status as a community consultant and intimate advisor This counseling function of the physician extended to such areas of community life as politics, economics, welfare services, institutional programs, and a great many other areas of social organization for which the study of medicine, per se, did not prepare him That American physicians have, in most instances, met the challenges outstandingly has been due to the attractiveness of the profession to those who possessed broad community ideals and leadership qualities suitable to the occasions

• *The role of organized medicine and its influence in determining health matters has been lessening, one reason being the diminishing intimate relationship between the patient and the general practitioner As the pre-eminent advisory group in health matters, medical societies have not been the active participants in community affairs which they ought to be The result has been that nonmedical persons and groups are more concerned with whether the local medical society will oppose a health suggestion than they are in getting the active support of the medical fraternity for it The experiences of some organizations in dealing with medical societies has occasionally been such as to preclude their approaching of the societies directly*

There would seem to be a need for many societies, as a first step, to affirm their willingness and readiness to cooperate fully with all groups in the consideration of community problems which are of direct, or even indirect, interest to the profession Community agencies are not frequently as concerned about the personal opinions of the medical man as they are about the attitude of the organized medical group which he represents An alert community, like nature, abhors a vacuum, and will find health leadership from other resources if such leadership is not proffered by its own medical society

We are rapidly recognizing that the dependence of the public on the medical practitioner for leadership in nonhealth areas has been undergoing a change As a matter of fact, the role of organized medicine and its influence in determining health matters has been lessening The reasons for these changes include, among others, a less intimate relationship between the patient and general practitioner, the public's recognition of the increased specialization of the medical arts and its willingness, in society generally, to consult a specialist in the topic or subject of concern, and, in particular, the development of the public health and paramedical sciences Laymen deciding important community health affairs will, in addition to consulting competent physicians, seek the advice of sanitary engineers, hospital administrators, public-health educators, community organizers, and others whose training qualifies them as experts Community decision-making processes are further affected by the thinking of unions, civic organizations, political factions, and a number of other groups, not all of which are readily identified by the community The development of a mass of citizenry which has been subjected to public health educational techniques and battered by a colossal amount of medical information in popular literature has also resulted in a degree of misinformation which tends to lessen the public's dependence upon medical physicians This change in the role of the physician and the professional societies in deciding

---

Executive Director (Mr MacDonald) and Chairman (Dr Cooper), Health Division of Council of Community Services health issues on behalf of fellow citizens has had implications for the individual practitioners and the medical societies which have not, in our opinion, been fully realized.

The emergence of national and local specific disease societies and causes, with their thousands of state and local affiliates or chapters, each with lay-dominated boards of directors, fund-raising programs, and hosts of financial contributors, has had a very real bearing on community health planning. This growing field of the voluntary health organizations is demonstrating an American innovation for attempting to meet certain health needs of our population. If this method fails, there appears at this time to be only one alternative for satisfying the voter's demands for health security—greater involvement by the taxing authorities at all levels of our society.

Americans, individually and as a nation, are rapidly accepting and integrating the medical opinions, information, and propaganda to which they are being increasingly exposed. And yet, the achievement of desirable programs, institution of orderliness in meeting major health needs, financing of medical care, and effectuation of our common goals is being frustrated because of the lack of leadership, the inability to use channels of mutual planning and coordination on the part of the many organizations concerned, and the general lack of a concerted approach to these problems by, among others, physicians and medical societies.

The Medical Society

The function of the medical society as the guardian of professional mores is completely accepted by a public which is becoming aware of the existence of grievance and other committees. Its interest in maintaining professional standards of education and preparation for practice is also understood, although this concern is sometimes referred to as a reflection of ‘closed shop’ thinking. As the preeminent advisory groups in health matters, the societies have not been the active participants in community affairs which they ought to be. This is particularly noticeable in local affairs where a society is lacking the stimulus of a national or state society directive or policy. In effect, nonmedical persons and organizations are more concerned with whether the local society will oppose a suggestion than they are in getting the active support of the medical fraternity for it. This is essentially a negative appraisal—too often confirmed in actual practice.

The frequent failure of organized medicine to involve itself in the early stages of all significant community endeavors is, in part, possibly the consequence of a lack of vision on the part of medical leaders. At the same time, there often does not exist an appropriate channel within societies whereby attention can be given to incipient situations.

Further, the experiences of other organizations in dealing with some medical societies has occasionally been such as to preclude their approaching the societies directly. In many communities, the local society appears to be concerned about community affairs (as far as the public is aware) only in terms of avoiding adverse publicity or maintaining the control or conduct of a jealously guarded project. In general, organized medicine at the local level, where its members also constitute themselves taxpayers, parents, civic leaders, and parishioners, frequently has failed to establish vital relationships with other groups or well-understood channels and methods for real participation in community health planning and programming. An alert community, like nature, abhors a vacuum and will find health leadership from other resources if such leadership is not proferred by its own medical society.

To secure the necessary further extensive and effective involvement in community health planning by the medical practitioner and his professional organization, societies should appreciate that they are being required, by the urgency which other groups feel, to establish methods of communication and procedures whereby the concerned bodies, public or voluntary, can secure generally representative opinions and answers to specific questions addressed to organized medicine. There would seem to be a need for many societies, as a first step, to affirm or reaffirm publicly and through channels their willingness and readiness to cooperate fully with all other concerned groups in the local consideration of community problems which are of direct or indirect interest to the profession. A genuine affirmation can be made only when a society is prepared to adopt the principle that all concerned have an opportunity to express opinions, however divergent or unacceptable these may be to medical men. Our political democracy requires that every organization demonstrate, by its own actions, its belief in our dictums.

Nor can a medical society too rigidly predetermine those areas or matters in which it ought, or is willing, to be consulted. Whenever a subject is broached to a society by responsible community forces, the courtesy of a considered reply is necessary, even if the reply constitutes a rejection. Society tends to progress, and progress is inevitably accompanied by change. Those groups which are too identified with the maintenance of the status quo or are irrationally opposed to change tend to find themselves negated by other social forces and relegated to ineffectiveness when change is contemplated. Neglect or refusal to adapt itself to the pattern of planning being developed in its community can be harmful to the best functioning of a local society.

As a means of implementing a society's participation in community planning, we suggest that the societies consider the desirability of establishing a standing committee to be known as the ‘community services committee’ or some similarly appropriate designation. This committee would have to be composed of experienced, active, and enthusiastic persons and would attempt to provide a channel through which requests from the community for medical personnel, opinion, or support might be given consideration.

The committee could act as a medium for gathering information and should be constantly aware of the status of all public or confidential proposals and programs in the community in which the professional body has an active or limited interest. Agencies, organizations, and civic groups would be willing to use such a depository of information, although its primary purpose would be to relate such data to the policies of the medical society. Someone has reminded us that Noah built the ark before the flood—the societies should be aware of what is going to happen in community health affairs before it occurs The committee could function as an advisory body to the board of directors of a society on problems in connection with temporary organizational representation between the society and other groups, public or voluntary

It could recruit, nominate, evaluate, and provide liaison in providing interested and competent physicians to serve on the boards of directors or policy-making committees of public or voluntary bodies desiring such personnel Implied here is the hope that some order may be brought into the confused situation which everyone recognizes A limited number of willing physicians are now required to involve themselves extensively (and sometimes unsatisfactorily) in the affairs of many groups, while others refuse these challenges or are unrecognized as potential leaders The committee might well undertake the assignment of members, for specific periods of time, to agency boards, committees, study teams, and other community groups in which it is important that medical professional opinion be expressed Younger physicians, new to the community or lacking experience, could be exposed to gradually increased responsibilities and more significant assignments Older physicians who, while most active, have found their energy dissipated in many groups might indicate their preference for extensive involvement in limited areas of interest

A periodic analysis of the collective contribution which the medical fraternity is making to its community could be brought to the attention of the public, possibly through the public relations committee and the new community services committee The professional organization gains little when a large percentage of its members, as individuals, give uncounted man-hours to the community through services on boards, committees, or projects Few medical societies have undertaken any study of the genuine contributions thus rendered to community well-being Not many organizations can afford to miss this opportunity to reinforce their own standing and the prestige of their members

The new committee could provide a means whereby physicians would have at hand a source of help, counsel, and opinion in certain matters Experienced physicians, aware of the history of particular organizations, understanding the psychological and cultural dynamics which impel well-known community leaders (including other physicians), informed about undercurrents of community life and the interorganizational and intra-agency relationships could do much, through the committee, to increase the value of individual members representing the society

Another function of the new committee could be to advise the board of directors of a society in matters of community service affecting the total membership Such problems as whether contributions to charity should be solicited from individual doctors or whether the professional body should assume responsibility could be considered by the committee

The Physician

Although the leadership of the professional medical body may wish to involve the society more extensively in community health and welfare planning activities, the key to its success is the individual member of the society When, as a medical person, an individual is a member of the board of directors or a policy-making committee of a voluntary agency or a public service, he is engaged in community planning In too few cases is he aware of the impingement or scope of policies which he has helped decide Frequently, a group decision in one area of community life has ramifications in other areas and the effects are not immediately forseeable The individual physician must, therefore, be prepared to subordinate himself to his colleagues in matters of community health and welfare services in an effort to increase his own effectiveness and the efficiency of his organization

Space does not permit a full consideration of the point that every physician is considered by the public to be a representative of his medical society In part, this attitude exists because the informed public is well aware of the fact that the society assumes responsibility for the ethics and quality of performance by its members Lay persons are also aware of the extent to which, at the national, state, and local levels, organized medicine has evolved and has stated policies and opinions Most physicians are constantly on the alert against any infringement of their civic or personal rights and responsibilities as different from those concomitant with membership in the medical society The line between them, if there can be one for professional persons, is exceedingly thin and capable of much confusion in delineation To the lay public, each reputable physician is presumed to reflect the aggregate opinion and attitude of the whole professional group and is, ipso facto, granted a psuedorepresentativeness when he is not an official spokesman of the society to which he belongs

A personal and sincere reevaluation of the contribution he is making in the life of his community's agencies will help the physician to assess more clearly the primacy and importance of his unofficial role as a representative of his medical society Community agencies are not, frequently, as concerned about the personal opinions of the medical man (except where appropriate to medical treatment matters) as they are about the attitude of the organized medical group which he represents In most cases, membership on a board of directors or the policy determination committee of an organization is extended to a physician not only because of his personal qualities but because he is a qualified medical practitioner and member in good standing in his medical society Few physicians will claim superior talents in, or a deep knowledge of, the complexities of voluntary agencies' administration, financing, or services Still fewer will claim intimate awareness or expert status regarding the conduct of public health services The agencies realize that there can be as many individual opinions about a specific matter as there might be physicians consulted The important factor to voluntary and public bodies is the stated stand or formal consensus of the whole professional organization on a particular issue

It remains for all physicians to realize this fact and to accept available assistance and guidance through a formalized relationship within the society This should not lessen the individual's contribution or sense of satisfaction Indeed, it should make him more comfortable and secure in the knowledge that he is a formal representative and supported by his society in his efforts

The conscientious physician should be willing to allow a committee of his peers to assess his qualifications for a particular task in any public or voluntary agency This carries with it a willingness to accept new assignments of increasing difficulty and to seek the guidance of his fellow practitioners in a formal manner whenever it may be required The alert medical man will be continuously aware of the stated policies of his society and interpret these clearly and diplomatically at appropriate moments He should also assume responsibility for seeing that his society states new policies as required and that these are communicated to all concerned as promptly as possible

Those physicians overextended in community life must be prepared to relinquish some of their activities to other physicians and, if desirable, devote themselves more intensively and purposefully to the achievement of the goals of fewer organizations Lastly, every physician should be personally prepared to accept responsibility for some participation as a representative of his medical society, should encourage all physicians to engage in community affairs, and should see these opportunities as challenges to himself, his fellows, and his profession

Summary

Organized medicine in America is losing some of its status and function as the paramount health advisor to local communities This is because it has not defined clearly new ways of participating most effectively in community health planning at the local level Each local medical society should establish a special working committee to coordinate the participation of the society and its members in local health and welfare planning and policy determination Individual physicians are unaware of their pseudorepresentativeness as members of local medical societies and should, in the interests of the profession, be prepared to subordinate personal interests and activities in regard to health and welfare agencies to the direction of their colleagues and peers in the society

CLINICAL NOTES

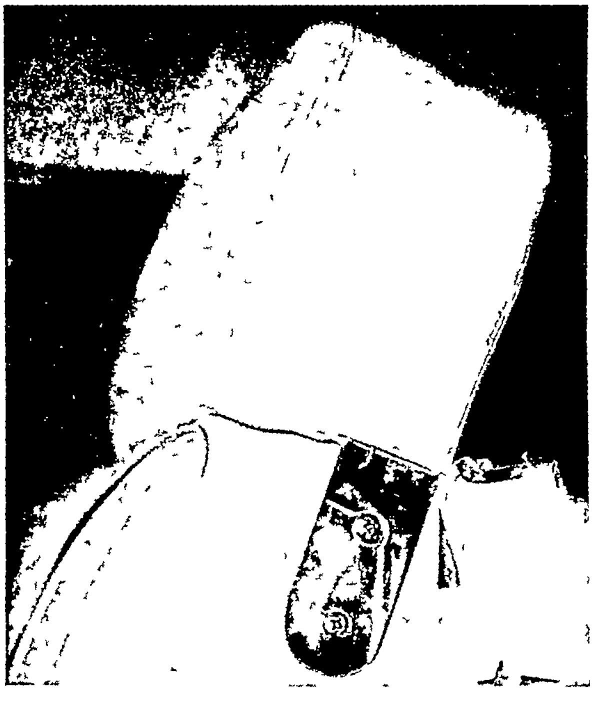
AUTOMOBILE SAFETY DEVICE—HEADREST TO PREVENT WHIPLASH INJURY

Albert D Ruedemann Jr, M D, Detroit

One of the more common forms of injury following automobile accident is the so-called whiplash injury of the cervical spine and musculature This injury usually results from a blow to the back of the automobile in which the individual is riding, causing first a forward movement of the body, followed by a rapid back-snapping of the head This results in an injury to the neck There are several reasons for this The first is a result of the change in the automobile seat to accommodate the new lower models The seat has also diminished in height, allowing a greater area of the body to be above the top of the seat Second, the advent of expressways and super highways with congestion of traffic at entrances and exits makes the chain reaction accident a more common occurrence

In order to prevent occurrence of the above injury, a modified headrest about 6 in (15 24 cm) in height was made to fit on top of the present seat It is so constructed that it follows the line of the seat in order that the head might not rest comfortably during ordinary travel This is to prevent any desire on the part of the driver to rest his head and possibly become drowsy The width of the headrest is approximately 6 in, allowing the top part to strike the head at about occiput level This prevents untoward loss of rear vision Coupled with an outside rear mirror, the loss is negligible The headrest is screwed to the seat frame on each side by several screws and is removable In this case it was made to match the existing automobile upholstery It is used in conjunction with a shoulder-type seat belt which reduces the forward motion of the body from a rearward or forward blow and in conjunction with the headrest would greatly reduce rearward motion from a blow to the automobile from behind (see figure)

1633 David Whitney Bldg (26)



The headrest was made through the courtesy of Messrs E M Braden and L Q Brown of the Chrysler Sales Department, and Mr Mazey of the Chrysler Trim Department manufactured the device

COUNCIL ON FOODS AND NUTRITION

The following six papers were presented at the symposium "Fats in Human Nutrition," in New Orleans, March 15, 1957 This symposium was sponsored by the Council on Foods and Nutrition, with the cooperation of the Tulane University School of Medicine, Louisiana State University School of Medicine, New Orleans Graduate Medical Assembly, and Orleans Parish Medical Society These papers plus the panel discussion will be available soon in monograph form

PHILIP L WHITE, Sc D, *Secretary*

Introduction to Symposium on Fats in Human Nutrition

Interest in the role of fats in human nutrition has been stimulated markedly in recent years by research findings which suggest that dietary fat may be implicated in the genesis of atherosclerosis and coronary heart disease The possibility that dietary factors may influence a process that has been considered an inevitable consequence of aging is a real challenge to scientific investigation Thus far, many studies have been carried out in several species of animals and in man, as well as in basic biochemistry, but much remains to be learned The literature on fat metabolism, including relationships of dietary fat and serum lipids to disease of the blood vessels, is so extensive that it is difficult for the practicing physician to evaluate this mass of information The purpose of this symposium is to review the current status of knowledge in this field, to attempt to differentiate facts from hypotheses, to indicate controversial issues, and to suggest promising areas for future research It is hoped that such a review will assist the physician in meeting problems presented by his patients and in planning therapeutic regimens which may prove beneficial Although all the facts are not available as yet, findings to date can be weighed carefully and sane experimental approaches to therapy developed

Unfortunately, many premature, uncritical, and even erroneous statements have appeared in numerous nonscientific publications which are widely read The general public needs guidance from the medical profession in interpreting such articles

The impetus given to studies of fat metabolism should prove worthwhile regardless of whether or not a causal relationship is found between dietary fat, atherosclerosis, and heart disease It is anticipated that, within the next few years, intensive research will assist in solving many of the problems raised in this symposium

DIETARY FAT—ITS ROLE IN NUTRITION AND HUMAN REQUIREMENT

L Emmett Holt Jr, M D, New York

Interest in fats goes in waves, the current wave being stimulated by the possible relation of fat to atherosclerosis—an area I shall leave to others to discuss Instead, I shall call attention to certain other effects of dietary fat that are less in the public eye

Fats as a Source of Energy

Although beyond the scope of this paper, it is worthwhile to recall that not all fats yield the traditional figure of 9 calories per gram, that is only an approximation for average edible fats The energy obtainable from fat is a function of the length of the carbon chain The short-chain fatty acids yield less energy, tributyrin, for example, yields only 6 7 calories per gram

Fats and Physical Work

When caloric demands are high, it is well known that fat is a preferred food The discomfort from the additional bulk of a less calorigenic food is thereby avoided Less familiar are the observations of Deuel and his co-workers [1] and of Samuels and his associates [2] in rats indicating that a diet containing considerable fat improves capacity for work as compared to a fat-poor diet and gives greater swimming endurance when food is subsequently withdrawn Reproductive efficiency and lactation were also found by Deuel's group to be superior in rats on diets containing moderate amounts of fat

Fats and Caloric Efficiency

Forbes and co-workers [3] have shown in a series of publications that there is more efficient utilization of calories when fat forms a substantial fraction of the diet The economy in calories is about 5 to 10% Several factors may contribute to this result—absence of a specific dynamic effect when fat is added to protein as contrasted with the result when carbohydrate is added to protein, and also the possibility that fat participates directly in certain metabolic reactions that would require its production from carbohydrate were it not provided as such

---

From the Department of Pediatrics, New York University College of Medicine

Fats as Vehicles

It is well known that fats serve as vehicles for the fat-soluble vitamins, A, D, E, and K, but it is less well known that many of the flavors of familiar foods are due to minute quantities of substances intimately associated with fat The extraction of various foods with fat solvents may remove the flavor completely or affect it adversely The loss of flavor of fruits and vegetables when they are preserved is attributed in large part to oxidative changes in fatty components

For the fat-soluble vitamins it is a question of whether increased fat absorption "drags in" such vitamin as may be present, thereby increasing the absorption of the vitamin Although such effects have been reported, studies undertaken by our group[4] in children indicated that the absorption of fat and of vitamin A were quite independent processes and did not influence each other

Fats and the Activity of the Stomach

It is an old observation that fats stay in the stomach longer than other foods Both the secretion and the motility of the stomach are inhibited by fat The effect is produced by an inhibitory hormone, enterogastrone, which is liberated from the duodenal and jejunal mucosa when absorption of fat commences The effect varies with different fats, depending on their ease of absorption The value of this mechanism is debated The delay in digestion appears to have some virtue in situations where there is a long interval between meals in that hunger pains do not develop This was said to be a serious problem in the German army during World War I because of the shortage of fats

Advantage is taken of the hunger-dispelling property of fats in certain reducing diets, the purpose being to avoid nibbling between meals On the other hand, it is claimed that the tastiness of fatty foods and their high caloric content offset this More data are needed to settle the question as to whether a high-fat or low-fat diet works best, but from present indications it appears that differences between individuals may be important here

TABLE 1 —*Effect of Sudden Increase in Dietary Fat**

	Net Balance Gm, 3 Day Period		
	Protein	Ash	Water
High-carbohydrate diet (protein 101 fat 115 carbohydrate 730 Gm)	− 5 22	+3	+165
High fat diet (protein 103 fat 302 carbohydrate 320 Gm)	−11 98	−7	−906

* Data from Benedict and Milner[7]

A group of infants, studied by Hansen and associates,[5] who were allowed food at will took fewer calories on a high-fat regimen However, we were unable to confirm this in one infant recently studied by Lanman in our clinic (fig 1)

Fats and Resistence to Infections

Among clinicians, particularly among pediatricians, the impression prevails that a preponderance of carbohydrate food tends to predispose to infection and a preponderance of fat to protect The literature on this subject is voluminous, but the net information that can be accepted is very scanty Experimental studies done before the vitamin era have to be discounted, since the intake of fat-soluble vitamins was varied with the fat, and the studies published since have not given consistent results In Europe, the flare-up of tuberculosis during and after World War II is widely attributed to the shortage of dietary fat Overcrowding and shortages of protein were usually present also, and data are not available in which these other factors could be ruled out The Gerson-Hermannsdorfer-Sauerbruch diet, which included a high fat content among other features, had a considerable vogue in Germany for the treatment of tuberculosis in the prewar years, but little has been heard of it since

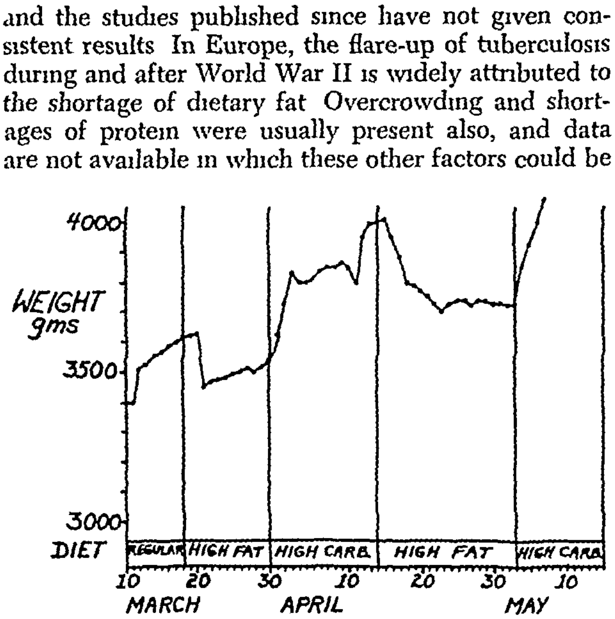

Fig 1 —Effect of fat and carbohydrate on weight of infant

Increased resistance to the common cold from a liberal-fat diet was claimed by Hoelzel[6] some years ago, but a large-scale statistical study to confirm this is still wanting There is no doubt that lipids play a role in immune processes and in permeability phenomena, but the relation to dietary fat remains to be established

Ketogenic Diets and Disease

Ketogenic diets have been used with success in a number of clinical conditions, notably urinary infections and epilepsy, and the mechanism of their action is of some interest In urinary infections, it appears that the benefit can be attributed to the concentration of acid in the urine that does not permit certain bacteria to survive The benefit obtained in epilepsy must be explained differently, it appears to be due to a measure of tissue dehydration brought about by the high-fat diet Such dehydration occurs whenever fat is substituted for carbohydrate and can be detected even before ketogenic levels are attained

The shifts of body water resulting from changing the proportions of fat and carbohydrate in the diet were known to the German physiologists of the last century and were well studied by Benedict and Milner[7] in the United States half a century ago (table 1) They are familiar to pediatricians and are illustrated in figure 1 The phenomenon of water loss in subjects on a high-fat diet is a temporary one, in three or four days a new equilibrium is established and the original weight gain is restored Conversely, when fat is re-

Interest in the role of fats in human nutrition has been stimulated markedly in recent years by research findings which suggest that dietary fat may be implicated in the genesis of atherosclerosis and coronary heart disease The possibility that dietary factors may influence a process that has been considered an inevitable consequence of aging is a real challenge to scientific investigation Thus far, many studies have been carried out in several species of animals and in man, as well as in basic biochemistry, but much remains to be learned The literature on fat metabolism, including relationships of dietary fat and serum lipids to disease of the blood vessels, is so extensive that it is difficult for the practicing physician to evaluate this mass of information The purpose of this symposium is to review the current status of knowledge in this field, to attempt to differentiate facts from hypotheses, to indicate controversial issues, and to suggest promising areas for future research It is hoped that such a review will assist the physician in meeting problems presented by his patients and in planning therapeutic regimens which may prove beneficial Although all the facts are not available as yet, findings to date can be weighed carefully and sane experimental approaches to therapy developed

Unfortunately, many premature, uncritical, and even erroneous statements have appeared in numerous nonscientific publications which are widely read The general public needs guidance from the medical profession in interpreting such articles

The impetus given to studies of fat metabolism should prove worthwhile regardless of whether or not a causal relationship is found between dietary fat, atherosclerosis, and heart disease It is anticipated that, within the next few years, intensive research will assist in solving many of the problems raised in this symposium

DIETARY FAT—ITS ROLE IN NUTRITION AND HUMAN REQUIREMENT

L Emmett Holt Jr, M D, New York

Interest in fats goes in waves, the current wave being stimulated by the possible relation of fat to atherosclerosis—an area I shall leave to others to discuss Instead, I shall call attention to certain other effects of dietary fat that are less in the public eye

Fats as a Source of Energy

Although beyond the scope of this paper, it is worthwhile to recall that not all fats yield the traditional figure of 9 calories per gram, that is only an approximation for average edible fats The energy obtainable from fat is a function of the length of the carbon chain The short-chain fatty acids yield less energy, tributyrin, for example, yields only 6 7 calories per gram

Fats and Physical Work

When caloric demands are high, it is well known that fat is a preferred food The discomfort from the additional bulk of a less calorigenic food is thereby avoided Less familiar are the observations of Deuel and his co-workers[1] and of Samuels and his associates[2] in rats indicating that a diet containing considerable fat improves capacity for work as compared to a fat-poor diet and gives greater swimming endurance when food is subsequently withdrawn Reproductive efficiency and lactation were also found by Deuel's group to be superior in rats on diets containing moderate amounts of fat

Fats and Caloric Efficiency

Forbes and co-workers[3] have shown in a series of publications that there is more efficient utilization of calories when fat forms a substantial fraction of the diet The economy in calories is about 5 to 10% Several factors may contribute to this result—absence of a specific dynamic effect when fat is added to protein as contrasted with the result when carbohydrate is added to protein, and also the possibility that fat participates directly in certain metabolic reactions that would require its production from carbohydrate were it not provided as such

---

From the Department of Pediatrics, New York University College of Medicine

Fats as Vehicles

It is well known that fats serve as vehicles for the fat-soluble vitamins, A, D, E, and K, but it is less well known that many of the flavors of familiar foods are due to minute quantities of substances intimately associated with fat The extraction of various foods with fat solvents may remove the flavor completely or affect it adversely The loss of flavor of fruits and vegetables when they are preserved is attributed in large part to oxidative changes in fatty components

For the fat-soluble vitamins it is a question of whether increased fat absorption "drags in" such vitamin as may be present, thereby increasing the absorption of the vitamin Although such effects have been reported, studies undertaken by our group[4] in children indicated that the absorption of fat and of vitamin A were quite independent processes and did not influence each other

Fats and the Activity of the Stomach

It is an old observation that fats stay in the stomach longer than other foods Both the secretion and the motility of the stomach are inhibited by fat The effect is produced by an inhibitory hormone, enterogastrone, which is liberated from the duodenal and jejunal mucosa when absorption of fat commences The effect varies with different fats, depending on their ease of absorption The value of this mechanism is debated The delay in digestion appears to have some virtue in situations where there is a long interval between meals in that hunger pains do not develop This was said to be a serious problem in the German army during World War I because of the shortage of fats

Advantage is taken of the hunger-dispelling property of fats in certain reducing diets, the purpose being to avoid nibbling between meals On the other hand, it is claimed that the tastiness of fatty foods and their high caloric content offset this More data are needed to settle the question as to whether a high-fat or low-fat diet works best, but from present indications it appears that differences between individuals may be important here

Table 1 —*Effect of Sudden Increase in Dietary Fat**

	Net Balance Gm, 3 Day Period		
	Protein	Ash	Water
High-carbohydrate diet (protein 101 fat 115 carbohydrate 730 Gm)	− 5 22	+3	+165
High fat diet (protein 103 fat 302 carbohydrate 320 Gm)	−11 98	−7	−906

* Data from Benedict and Milner[7]

A group of infants, studied by Hansen and associates,[5] who were allowed food at will took fewer calories on a high-fat regimen However, we were unable to confirm this in one infant recently studied by Lanman in our clinic (fig 1)

Fats and Resistence to Infections

Among clinicians, particularly among pediatricians, the impression prevails that a preponderance of carbohydrate food tends to predispose to infection and a preponderance of fat to protect The literature on this subject is voluminous, but the net information that can be accepted is very scanty Experimental studies done before the vitamin era have to be discounted, since the intake of fat-soluble vitamins was varied with the fat, and the studies published since have not given consistent results In Europe, the flare-up of tuberculosis during and after World War II is widely attributed to the shortage of dietary fat Overcrowding and shortages of protein were usually present also, and data are not available in which these other factors could be ruled out The Gerson-Hermannsdorfer-Sauerbruch diet, which included a high fat content among other features, had a considerable vogue in Germany for the treatment of tuberculosis in the prewar years, but little has been heard of it since

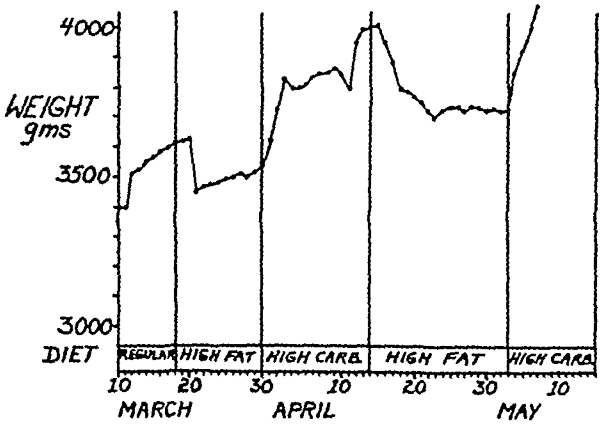

Fig 1 —Effect of fat and carbohydrate on weight of infant

Increased resistance to the common cold from a liberal-fat diet was claimed by Hoelzel[6] some years ago, but a large-scale statistical study to confirm this is still wanting There is no doubt that lipids play a role in immune processes and in permeability phenomena, but the relation to dietary fat remains to be established

Ketogenic Diets and Disease

Ketogenic diets have been used with success in a number of clinical conditions, notably urinary infections and epilepsy, and the mechanism of their action is of some interest In urinary infections, it appears that the benefit can be attributed to the concentration of acid in the urine that does not permit certain bacteria to survive The benefit obtained in epilepsy must be explained differently, it appears to be due to a measure of tissue dehydration brought about by the high-fat diet Such dehydration occurs whenever fat is substituted for carbohydrate and can be detected even before ketogenic levels are attained

The shifts of body water resulting from changing the proportions of fat and carbohydrate in the diet were known to the German physiologists of the last century and were well studied by Benedict and Milner[7] in the United States half a century ago (table 1) They are familiar to pediatricians and are illustrated in figure 1 The phenomenon of water loss in subjects on a high-fat diet is a temporary one, in three or four days a new equilibrium is established and the original weight gain is restored Conversely, when fat is replaced by carbohydrate, a sudden spurt in weight occurs for three or four days, after which the slope of the normal weight curve is resumed

This phenomenon has been studied particularly by Cathcart[8] in Glasgow and by his successor, Munro[9] Balance studies have shown that the shift in water retention is accompanied by a shift in both extracellular and intracellular electrolyte and that a labile nitrogen fraction accompanies this loss (tables 2 and 3) Partition of the urinary nitrogen excretion during the period of water loss reveals an increased loss of all nitrogenous constituents measured except uric acid, the excretion of which was curtailed at this time Conversely, during the period of increased water retention resulting from a high-carbohydrate diet, urinary loss of the major nitrogenous constituents is diminished but loss of uric acid is increased (table 4) The excretion of individual amino acids has not as yet been studied in this situation Thompson and Munro[10] have shown that this phenomenon is only indirectly attributable to the change in fat intake It can be brought about by changes in the carbohydrate intake alone, the fat being kept constant The significance of these changes remains obscure It is not clear that the individual burning a preponderance of carbohydrate is healthier than the less hydrated individual on the high-fat, low-carbohydrate regimen, but there are a number of indications that cellular reactivity is reduced in the relatively dehydrated state so induced The abnormal reactivity of the cerebral cortex of the epileptic appears to be so reduced and, conversely, a measure of overhydration tends to precipitate active epileptic seizures, as pointed out by McQuarrie and Peeler[11] The bronchial reactivity associated with anaphylactic shock in the guinea pig was shown by Rubin and Kellett[12] to be inhibited by dehydration Likewise Kulchar and Alderson[13] showed that the cutaneous response to micrococcic (staphylococcic) infection was inhibited by dehydration A similar effect may be observed in infantile eczema, which will be discussed subsequently

Fats and Water Requirement

The water requirement of persons receiving different foodstuffs is a matter of concern in situations of water scarcity, such as when persons are castaways at sea It is generally admitted that protein food is disadvantageous here because of the obligate urinary water requirement to excrete urea The excellent observations of Gamble[14] pointed to carbohydrate as the food of choice for the castaway because of an economy of water and extracellular electrolyte resulting from glucose administration It must be pointed out, however, that their periods of observation were all short—no more than six days, hence, the effects they observed may have been only the temporary shifts caused by carbohydrate which have been referred to previously Whether this advantage of carbohydrate would have persisted for the far longer periods to which the castaway may be subjected remains to be shown

Some observations of rats that were fed single foodstuffs[15] and allowed to regulate their water intake are of interest in this connection, since the experimental conditions lasted for the life span of the animals The water intake of these rats is shown in figure 2 The high demand for water by the animals fed protein is well illustrated, and equally clear is the lesser water intake when the rats were fed fat rather than carbohydrate One reason for this is that more metabolic water is supplied by fat Some of the higher water intake of the rats fed carbohydrate may have been due to the fact that the animals took more sugar than they could handle, for they spilled sugar in the urine, which would have increased their water requirement Certainly, these observations do not suggest a long-term economy of water resulting from carbohydrate as opposed to fat

Fats and Eczema

The literature on the control of eczema by varying nonprotein constituents of the diet is conflicting, and one variable at a time has seldom been studied There are favorable reports on withdrawing fat and equally favorable reports on adding it A more consistent finding is the disappearance of eczema associated with an acute febrile disease such as measles and its reappearance during convalescence It seems possible that the metabolic shift brought about by the fever, with dependence on fat and a deficit of available carbohydrate, might have caused this change in skin reactivity Some years ago we observed children on a fat-free diet[16] In one of these children, eczema and asthma appeared regularly when fat was removed from the diet and disappeared quite as promptly when it was restored We have since made use of the dehydrating effect of a high-fat, low-carbohydrate diet as an adjuvant in the treatment of eczema and have been impressed by the results

TABLE 3 —*Effect of Carbohydrate-Rich Diet in an Infant**

	Daily Balance Gm					
	N	Na	K	Ca	Cl	P
Normal diet	0.84	0 13	0 25	0 08	—0 05	0 08
High carbohydrate diet	1 60	0 22	0 39	0 09	0 0[illegible]	0 [illegible]0

* Data from Rosenstern I *Ztschr Kinderh* 18 333 1918

Another explanation must be considered, however, for the beneficial effect of such a diet Increasing the total fat intake also increased the intake of polyunsaturated fatty acids The view that they are the active agents in benefiting the disease and that eczema is the human counterpart of the essential fatty acid deficiency disease observed in several animal species is advocated by Hansen[17] Presently available information does not make it possible to decide the question To do that will require observations on the effect of a fat containing no polyunsaturated acids or observations on the effect of minute amounts of pure polyunsaturated acids with no change in the total fat intake

Fats and Poisons

The literature on poisoning contains many references to the value of major shifts of the calorigenic foodstuffs In some instances (for example, diphtheria toxin),[18] a high-protein diet is best, in other instances (chloroform, for example) [19] a high-carbohydrate diet, and in still others (cyanide, arsphenamine),[20] a high-fat diet With fat-soluble poisons, such as chloroform and carbon tetrachloride, the effect is unfavorable, but with others no generalization is possible

Fats and Radiation Injury

Of considerable interest are recent observations [21] indicating that polyunsaturated fatty acids will protect against x-ray injury The effect appears to be more pronounced for low-grade, repeated radiation than against a single large dose

Toxic Effects of Fats

No attempt will be made here to review the extensive literature on rancid fats, on various toxic natural fats (such as castor oil), or on hydrogenated fats Mention should be made, however, of certain alleged untoward properties of natural fats their ability to induce vomiting, their ability to induce intestinal intolerance, and their hemolytic properties

The statement that an excess of fat leads to nausea and vomiting is often made in the pediatric literature, however, excesses of other foods will do this also It may be true that a smaller excess of fat will cause nausea and vomiting than of other foodstuffs, possibly the specific inhibitory effect of fat on gastric motility predisposes to nausea and vomiting when an excess is given, but I have not been able to find documentary evidence of this

That the continued administration of generous amounts of fat would induce a condition of intestinal intolerance to fat was a belief strongly held by pediatricians a generation ago The evidence today is, however, strongly against this concept Haas [22] observed that the administration of liberal quantities of fat in celiac disease produced only benefit In a systematic study of several different forms of fat intolerance made by our group at New York University [23] it was shown by balance studies that the addition of fat in such cases failed to affect the percentage absorbed and consistently improved the absolute absorption figures Similar data have been reported in the steatorrhea of kwashiorkor by Gomez and co-workers in Mexico [24]

TABLE 4 —*Influence of Fat and Carbohydrate on Urinary Excretion of Purines in Human Subject**

	Nitrogen Gm /Day	Uric Acid Gm /Day	Total Purines Gm /Day
High carbohydrate diet (protein 50 fat 30 carbohydrate 443 Gm)	7 81	0 98	0 110
High fat diet (protein 50 fat 190 carbohydrate 80 Gm)	8 77	0 70	0 091

* Data from Umeda T *Biochem J* 9 421 1915

Considerable interest in the hemolytic properties of fat developed some years ago with the discovery that various hemolytic snake venoms were lipids Pernicious anemia and the anemia caused by the fish tape worm were at one time attributed to hemolytic lipids A better understanding of these conditions has exonerated dietary fat Nevertheless, there remains a small amount of evidence indicating that a minimum hemolytic tendency may result from great excesses of fat Josephs and his co-workers [25] investigated this question in infants, using total urobilin excretion as a measure of blood destruction, and were able to demonstrate consistent rises in the stool urobilin output when the calories derived from fat were raised from 35% to 80% of the total ingested The administration of free fatty acids and soaps produced this effect at lower levels of intake, but in no instance was the magnitude of the urobilin excretion comparable to that seen in any of the hemolytic anemias, nor was it sufficient to lead to anemia The phenomenon is actually a matter of academic interest Other recent evidence that dietary fat in large quantity may be hemolytic comes from Loewy and his co-workers,[26] who demonstrated a hemolytic principle in thoracic duct lymph and in lipemic serum after a high-fat meal

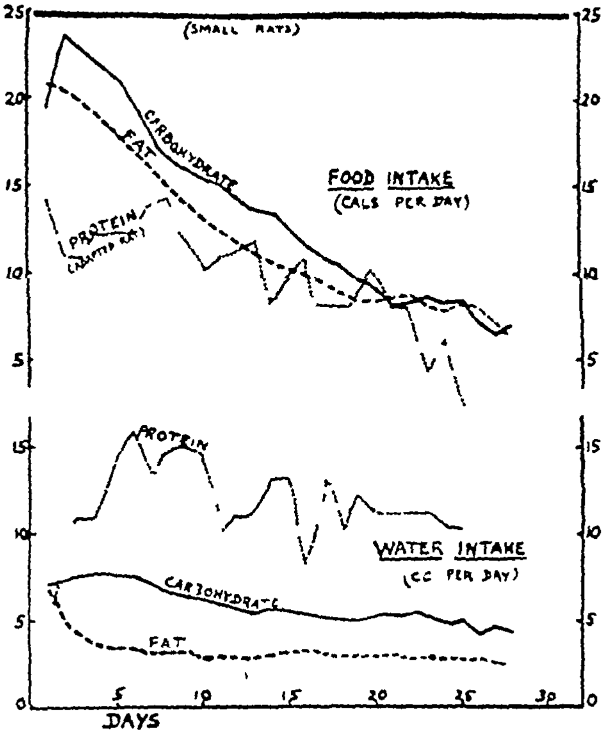

Fig 2 —Food and water intake of rats fed single pure foodstuffs

Minimal Fat Requirement for Man

There is no question about the essentiality of the polyunsaturated fatty acids for various animals, but the evidence of a human requirement for these compounds is as yet unconvincing Several long-term studies have been carried out with infants on fat-free diets Von Groer in 1919 fed two infants on fat-free milk The results were reasonably good for a period of six months, after which signs of rickets became evident and gain in weight suffered Eczema developed in one infant No fat-soluble vitamins were given to these infants

Von Chwalibogowski[27] some years later repeated von Groer's study in two infants, one of whom received ultraviolet irradiation to prevent rickets The study was started at birth and the feeding consisted of triply centrifuged milk (fat content less than 0 03%), a small amount of fat-free vegetable being added after the fifth month One child was continued on this diet for 13½ months and the second for 15 months The growth and development of these children were quite normal The child who received antirachitic radiation showed no evidence of rickets, but the untreated child showed some evidence of the disease The resistance to several intercurrent infections—grippe measles, and pyuria—did not seem to be impaired There was some loss of appetite toward the end of the study

Brown and his associates[28] reported observations on two older infants kept on a fat-free diet for 10 weeks whose only untoward manifestations were attacks of impetigo They also studied an adult who remained on the diet for six months The diet, however, contained at least 2 Gm of fat a day The subject of this experiment lost some weight at the start, his blood pressure, which had been slightly elevated, returned to normal, and migraine headaches disappeared The levels of arachidonic and linoleic acid in the blood fell somewhat, which led the authors to conclude that in time a deficiency of these acids would have declared itself

Hansen and Wiese[29] conducted what is probably the longest study of a human on a fat-free diet A small child with chylous ascites was kept on such a diet for a period of two years The general condition remained good, although a tendency to eczema and skin infections was noted

These observations certainly do not disprove the existence of a human need for essential fatty acids It may be that with a longer period of time or a more rigorous elimination of dietary fat, symptoms would have developed At the most they can be said to be suggestive of a vulnerability of the skin of a person on a fat-free regimen It is probable that a minimum requirement for polyunsaturated fatty acids exists in the human, but no exact figure on this minimum and no definite statement regarding its existence can be made at the present time

SOME BIOCHEMICAL ASPECTS OF LIPID AND LIPOPROTEIN METABOLISM

Donald S Fredrickson, M D, Bethesda, Md

The impetus given to research in lipid metabolism by the increasing interest in the problem of atherosclerosis has yielded a bounty of information in recent years The clinician and the nutritionist cannot escape a requirement for an ever-broadening familiarity with certain practical aspects of lipid chemistry and physiology The nature of dietary fat is becoming more meaningful than its simple caloric content, and determination of the plasma cholesterol level alone no longer represents an adequate examination of the blood lipids It is the purpose of this paper to summarize some aspects of our basic knowledge concerning lipid transport mechanisms and fat metabolism that are of clinical importance

Blood Lipids and Lipoproteins

In 100 cc of plasma of a normal fasting human, there is about 300 mg of fatty acids Roughly 80% of these fatty acids are present in phospholipids or in simple esters of glycerol This latter group of esters is usually referred to as "triglyceride (which is preferred to the term "neutral fat") even though small, variable amounts of diglycerides and monoglycerides are also present Another 15% of the fatty acids are esterified with cholesterol, and a highly significant 5% circulate unesterified and bound to protein The type of fatty acid present in any one of these lipid moieties is variable, depending, among other things, on the nature of the diet and on the composition of the body fat depots The fatty acids esterified with cholesterol are relatively more unsaturated than those of the phospholipids or triglycerides

All of the plasma lipids, which include some unesterified cholesterol in addition to the moieties containing fatty acids, are too insoluble in water to exist in simple solution in the tissue fluids Therefore, all of the lipids are transported in combination with protein and, presumably, in that form are capable of entering into biological reactions In plasma and lymph, cholesterol, phospholipid, and triglyceride are found in association with globulin, forming macromolecules called lipoproteins Whereas some of the unesterified fatty acids have been described as present in the lipoproteins, the bulk of them circulate in plasma, presumably bound to albumin Thus, a large family of lipid-protein complexes have been isolated from plasma and partially characterized A convenient grouping into major fractions on the basis of present evidence of chemical or physiological uniqueness is shown in table 1

These fractions are listed in table 1 in the order with which they would be obtained by repeatedly centrifuging plasma at high speeds with serial increases in density by methods [1] based on the original observations of Lindgren, Gofman, and Elliott [2] The application of several techniques that utilize different physical properties of the lipoproteins to effect their separation has produced some overlapping and confusion in terminology By electrophoresis, broad classes of "beta," "alpha$_1$," and 'alpha$_2$" lipoproteins have been separated The technique of Cohn fractionation, based on differential solubility, also permits isolation of similar broad groups It is to Gofman and his colleagues that we are indebted for refinements of ultracentrifugal techniques that permit the most complete separation of the lipoproteins [3] In their classification the lipoproteins fall into two great groups, most simply termed the low and high density lipoproteins The low density lipoproteins, which include the beta and probably the alpha$_2$ lipoproteins, are further separable into a whole spectrum of classes lying within certain Svedberg flotation unit (S_f—used to express the positive migration rate for lipoproteins undergoing flotation in an ultracentrifugal analysis) values that ascend numerically with increasing rate of flotation in the centrifugal field This property is, in turn, dependent upon decreasing density of the lipoprotein molecules For simplicity, these classes are placed in two groups in table 1, and termed arbitrarily very low density ($S_f > 10$) and low density (S_f 0-10)

TABLE 1 —*Major Lipid Protein Fractions in Plasma*

	Terminology			
Fraction	Sf*	—S†	Electrophoresis	Cohn‡ Fractions

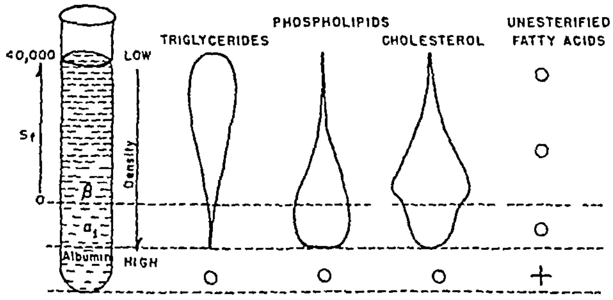
Low density lipoproteins	0-10	25-40	β	III 0
High density lipoproteins		1 10	α_1	IV 1
Albumin unesterified fatty acids				V

* Gofman [3]
† From Lewis and Page *Circulation* 7 707 1953
‡ Oncley and others [4]

Studies, principally by the Gofman group, indicate that there may be many more species within the very low density lipoproteins that have distinct metabolic behavior The high density lipoproteins, which include the alpha$_1$ lipoproteins, also are not homogeneous but represent at least two or three species, the concentrations of which vary independently under certain conditions The chylomicrons are considered separately because they normally are present only when large amounts of absorbed fat, principally as triglyceride, are entering the blood from the thoracic duct Accurate analysis of the protein moiety of the chylomicrons has not yet been reported, and their exact chemical and physiological relationship to the very low density lipoproteins is not known The albumin-unesterified fatty acid complex, which is not strictly a lipoprotein, completes the list

The physical structure of the lipoproteins, which permits the solubilization of many molecules of lipid by few molecules of protein, can only be speculated upon from existing information From the data of Oncley, Gurd, and Melin [4] concerning the beta lipoproteins corresponding approximately to the S_f 0-10

From the National Heart Institute, National Institutes of Health Public Health Service class, it would appear that these macromolecules may be large spheres containing lipid, predominantly cholesterol and phospholipid, partially covered by a thin film of protein Probably the lipid moieties are bound to each other and to the protein by Van der Waal's forces An important constituent of the macromolecular structure is water, because dehydration destroys the stability of the molecule From work in our own and other laboratories it is apparent that the lipids of the lipoproteins exchange freely with other lipoproteins and are readily accessible for enzymatic reactions such as hydrolysis



Schematic distribution of blood lipids and lipoproteins

The chemical distribution of the plasma lipids with relationship to the lipoproteins is represented schematically in the figure Here the lipoproteins are presented as they might be obtained in a highly theoretical gradient tube, with lowest density components at the top and increasing density moving downward Albumin, and not the remaining plasma globulins, is shown at the bottom to emphasize the probable role of this protein as the carrier of most of the unesterified fatty acids Analytical values for some of the fractions are shown in table 2 The most striking feature is the inversely proportional concentrations of triglyceride and of protein in the lipoproteins Those of lower density are large, scatter light, and impart turbidity or lactescence to the serum when they are present even in low concentrations The lipoproteins of higher density are rich in cholesterol and phospholipid, but in differing proportions

Although the measurement of lipoprotein concentrations by eye is impossible, the relationships emphasized in the figure give some information about abnormal lipid and lipoprotein concentrations from the appearance of fasting serum, particularly when a simple cholesterol determination is also available For example, as a general rule, when the serum cholesterol level is elevated the increase will be reflected in increased concentration of the low or very low density lipoproteins When marked elevations occur in perfectly clear serum, the low density lipoproteins (S_f 0-10) will be elevated, and the serum will likewise usually take on a deeper yellow color from the added carotene carried by this fraction For unknown reasons, patients with essential hypercholesteremia and this 'xanthoma tendinosum pattern'[5] in the serum will tend to develop tendon sheath xanthomas Lactescence implies elevated triglycerides and increased amounts of the lower density, higher S_f lipoproteins Gofman has popularized the term "xanthoma tuberosum pattern"[5] for this picture, and the clinical correlation of this type of lesion with persistently elevated triglyceride levels is impressive Persons with essential hypercholesteremia may, of course, have both types of xanthomas simultaneously The most marked turbidity occurs in idiopathic hyperlipemia, where the bulk of the triglyceride-rich lipoproteins may be chylomicrons Lactescent serum is not always accompanied by remarkable elevations in the total serum cholesterol level, since the percentage of cholesterol in the chylomicrons and other very low density lipoproteins is small (table 2) Thus, some patients with idiopathic hyperlipemia may escape diagnosis for years until an observant person takes note of the appearance of the serum Unfortunately, today's centralization of laboratory facilities, by separating the physician from a glimpse of his patient's serum, denies him a small, but interesting, diagnostic opportunity

Lipoprotein Metabolism

At present, only a little is known about the specific metabolic functions of the lipoproteins and the physiological relationship of one lipoprotein class to another It appears that the unifying hypothesis of a single "parent" molecule, such as the chylomicron, which would simply be shorn of more and more of its triglyceride to become lipoproteins of successively decreasing size and greater density, is not tenable for the whole lipoprotein spectrum, although it may be true for part One of the principal means of studying lipoprotein "genealogy' has been through the lipoprotein protein moiety Analyses of the low density and high density lipoproteins indicate that their constituent proteins are similar, but not identical,[6] and these two great lipoprotein groups are probably not interconvertible Gofman's group has presented considerable presumptive evidence of interconversion of very low density lipoproteins from higher to lower S_f classes[3] By actual labeling of the protein moieties, Gitlin and Cornwell[7] have shown more conclusively that very low density lipoproteins of $S_f > 10$ are converted to low density lipoproteins of the S_f 0-10 class, which then disappear with a half-life of about 3 days Presumably this takes place simply by loss of triglyceride

TABLE 2 —*Approximate Percentage Composition of Several Lipoprotein Fractions**

Fraction	Protein	Tri glyceride	Choles terol	Phospho lipid
Chylomicrons	2	81	9	7
Very low density lipoproteins (S_f >10)	7	52	22	18
Low density lipoproteins (S_f 0-10)	21	9	47	23
High density lipoproteins	46	8	19	26

* From Bragdon and others *J Lab & Clin Med* 48 36 1956

The chylomicrons are normally of great metabolic importance only transiently They disappear rapidly from the blood after they enter from the lymph There is some evidence in humans that they might be serially converted to lipoproteins down to the class of S_f-30 low density lipoproteins during the disappearance of alimentary lipemia[8] On the other hand, studies in dogs suggest that chylomicron triglycerides labeled with radioactive carbon (C^{14}) may first disappear into unknown organ sites, where they are rapidly hydrolyzed and their constituent fatty acids rapidly returned to the plasma for retransport bound to albumin[9]

The "clearing" of alimentary lipemia, which implies the disappearance of the light-scattering chylomicrons and very low density lipoproteins from the plasma, has received much attention from the clinical standpoint The important biochemical reaction involved in "clearing" is the hydrolysis of triglyceride The enzyme system that probably catalyzes this reaction under physiological conditions has been partially characterized The isolation by Korn[10] of an enzyme from heart and adipose tissue that has identical properties to the 'clearing factor" found in plasma after the administration of heparin has led to the adoption of his newer term, "lipoprotein lipase,' for this factor The properties of lipoprotein lipase may be summarized as follows

Substrate Triglycerides + Lipoprotein Lipase →
Enzyme-Substrate Complex + Albumin or Ca^{++} →
(Albumin or Ca^{++}) Fatty Acids + Glycerol (or Diglycerides Monoglycerides)

(Substrates include the triglycerides of chylomicrons and very low density lipoproteins, or of synthetic emulsions that have first been incubated with small amounts of nonspecific plasma or egg lipoproteins)

This enzyme catalyzes the hydrolysis of triglyceride in any lipoprotein It is significant that synthetic triglyceride emulsions are also split, but only after small amounts of any nonspecific lipoprotein are first bound to the emulsion by incubation This suggests that the small amount of protein, phospholipid, and perhaps cholesterol in the chylomicron, for example, is of the utmost importance for these lipoproteins to function as substrates The reaction will proceed when there is adequate receptor to bind the product of fatty acids This is largely albumin when hydrolysis takes place within the plasma This enzyme may have widespread function in the removal of alimentary fat, the interconversion of lipoproteins, and the release of unesterified fatty acids from depot fats

The relationship of heparin to "clearing" is extremely interesting Korn has shown that heparin, or a similar compound, is actually an intimate part of the lipoprotein lipase molecule or complex With some few exceptions, when present methods are used, lipoprotein lipase activity is normally very low or not even detectable in the blood, even when large amounts of fat are being cleared Therefore, lipoprotein lipase activity in tissues, rather than in the blood, is probably of far greater physiological importance For unknown reasons, the parenteral administration of heparin and a few other compounds causes the enzyme activity to appear quickly in plasma, where hydrolysis occurs with production of glycerol and fatty acids, and the concentrations of higher S_f lipoproteins decline while those of the lower S_f molecules rise[3] Tests of "clearing" in plasma after heparin injection, however, are hard to interpret clinically One pitfall to interpretation is the variability of substrate lipoproteins present in the plasma in any group of individuals given heparin The enzyme activity that appears in the blood may not then be accurately measured by observing changes in optical density alone So far, only three hyperlipemic patients, in the same family, have been reported who demonstrate practically no plasma lipoprotein lipase activity, as measured by glycerol or fatty acid production, after large doses (100 mg) of heparin[11] It remains to be proved whether or not altered activity of tissue lipoprotein lipase or of heparin is the cause of any other lipid disorder, or that the reported clinical effects of heparin in coronary artery disease are operating through the lipoprotein lipase mechanism

Most of the work on the unesterified fatty acids of plasma is so recent that their clinical significance has not yet been assessed They appear to be of such metabolic significance, however, that they must be mentioned Studies by Dole[12] and by Gordon and Cherkes[13] indicate that the plasma concentration, which is normally in the neighborhood of 0 3-0 6 mEq per liter after an overnight fast, is higher in conditions associated with the increased burning of fat, such as fasting, and rapidly decreased by the ingestion of carbohydrate or other nonfat caloric sources In the fasting human, as much as 70% of the calories being used by the heart may be derived from unesterified fatty acids The evidence suggests that it is in this form that fat is primarily transported from the (adipose) depots to other tissues for oxidation as energy sources The turnover rate in blood appears to be very high,[9] and the fatty acids are rapidly transferred across the endothelium even though their binding to albumin is very strong It is conceivable that a quantitatively small defect in the normal transport of fatty acids might be associated with significant changes in the other forms of lipid transport

Lipoprotein Metabolism and Disease

Abnormal lipoprotein concentrations are now known clinical features of many diseases Usually it has not been determined whether the lipoprotein changes are due to specific defects in lipoprotein metabolism per se or to underlying alterations in tissue metabolism of fats that are secondarily reflected in increased or decreased transport of the various lipids One interesting possibility in the first category is the observation by Gitlin and Cornwell[7] that the normal conversion of very low to low density lipoproteins was impaired in several patients with the nephrotic syndrome This could account for the abnormal concentrations of very low density lipoproteins seen in some patients with this disease A second example probably belonging in this category is liver disease, such as xanthomatous biliary cirrhosis, which may inexplicably be accompanied by very low concentrations of high density lipoproteins, even though the serum cholesterol level may be abnormally high The increases in the lower density lipoproteins that are seen in untreated diabetic acidosis and glycogen storage disease probably belong in the second category In these states excessive amounts of fat are required for metabolism through a defect in carbohydrate utilization It may be postulated that, in addition to high turnover of unesterified fatty acids, large quantities of triglyceride are also being transported to participate in the necessary change in the metabolic pool When the diabetic acidosis is treated the abnormal lipoprotein concentrations promptly fall Reciprocal changes in lipoprotein concentrations also are perplexing clinical findings sometimes seen in patients with severe transient or persistent hyperlipemia In idiopathic hyperlipemia, for example, when the very low density lipoprotein concentrations are high, the total high density lipoprotein concentration may be very low, rising as the concentration of the former is lowered by diet or heparin therapy The causes for other important changes in lipoprotein concentrations remain unsolved Only two of these will be mentioned further One, the difference in concentration between the sexes, is of great interest, the other, the changes present in atherosclerosis, is perhaps of the greatest importance

The major differences in lipoprotein concentrations between men and women in the ages from 15 to 65 is a higher concentration of all the major low density lipoprotein classes and a lower total high density lipoprotein concentration in the male As demonstrated by Russ, Eder, and Barr[14] and others, the administration of estrogens to men causes the lipoprotein pattern to resemble that of the premenopausal female Testosterone opposes this effect and produces an exaggeration of the male pattern

The evidence that patients surviving a myocardial infarction have elevated levels of lower density lipoproteins, especially of the S_f 12-400 classes,[3] as first proposed by Gofman, is highly significant The relative value of the serum cholesterol as compared with the lipoprotein measurements or "atherogenic index" in predicting the likelihood of development of clinical manifestations of atherosclerosis appears to be still a matter of controversy[15]

Reduction of Hypercholesteremia by Biochemical Agents

The association of elevated levels of cholesterol or cholesterol-rich lipoproteins with atherosclerosis has focused attention on means of lowering the serum cholesterol level The dietary approach to this problem has been covered adequately elsewhere in this symposium Since attacks by means other than diet are under study and in clinical use, several of these should be mentioned briefly

The use of plant sterols, such as sitosterol, has been reported extensively in the literature Some workers report moderate reduction in the serum cholesterol level from 10-20%, others find less consistent results Rarely are they effective in reducing the cholesterol level to normal in patients with essential (familial) hypercholesteremia The mechanism of action of these sterols, which closely resemble cholesterol in structure, is not completely known, although it is postulated that they interfere with intestinal absorption of exogenous cholesterol or of the reabsorption of endogenous sterol Certain aromatic acids have been given wide clinical trial, particularly in Europe, with reported success[16] These compounds do have significant inhibitory effects on the synthesis of cholesterol from acetate, apparently by interfering with acetylation reactions involving coenzyme A[17] However, this inhibition usually is not reflected in lowered plasma cholesterol levels in rats Clinical trial with two of these compounds, alpha-phenylbutyric acid and beta-phenyl levaleric acid, failed, in our hands, to cause any lowering of the cholesterol level in patients[18] This disparity between biochemical activity and clinical effect is very likely due to the fact that these particular compounds are inhibiting synthesis at so early a step in the conversion of acetate to cholesterol that other precursors normally supplied by the body will not be affected For this reason attention is being turned to compounds that are much closer to cholesterol in structure Some such compounds already have been shown by Tomkins, Sheppard, and Chaikoff[19] to inhibit the synthesis of cholesterol from acetate One of these, Δ 4-cholestenone, has been found to lower the serum cholesterol level in animals[20] This is associated with serious side-effects, however, and all such compounds, particularly since they, too, might participate in atheroma formation, will have to be proved to be nontoxic before they can have clinical value Since the biochemical knowledge of the normal pathways for the synthesis and degradation of cholesterol is now reasonably good, there is hope that in the future some effective chemical hypocholesteremic agents may be found as adjuvants to present dietary therapy

The biochemical and physiological developments mentioned all signify progress in clarifying the mechanisms of lipid metabolism and transport On the subject of fat, the nutritionist, the clinician, and the biochemist are rapidly approaching common ground, and on such favorable terrain, our understanding of the role played in health and disease by this important constituent of diet and of body tissues can only continue to grow

Summary

The metabolism of fat and the mechanisms of fat transport have been investigated intensively in the search for a key to the cause of atherosclerosis A group of lipid-protein complexes that represent the form in which fat is normally present in the blood and lymph have been elucidated These complexes include the lipoproteins and the albumin-bound unesterified fatty acids Certain of the lipoprotein classes have special clinical significance in relation to atherosclerosis and the hypercholesteremic and hyperlipemic xanthomatoses There are variations in lipoprotein concentrations in such conditions as diabetic acidosis and the nephrotic syndrome that are not only of clinical interest but that also suggest a metabolic function for the very low density lipoproteins The process by which newly absorbed fat is removed from the blood is now partially understood Hydrolysis of triglycerides catalyzed by the enzyme lipoprotein lipase is probably an integral part of the 'clearing process' Heparin, which causes lipoprotein lipase activity to appear in the blood, may form part of the actual enzyme complex Decreased plasma lipoprotein lipaase activity has been correlated with at least one form of hyperlipemia The plasma unesterified fatty acids, which are the only blood fats which circulate bound to albumin, appear to be of great importance in the transport of fat to the tissues to be oxidized This fraction of the plasma lipids may have future clinical significance

PATHOLOGICAL LESIONS RELATED TO DISTURBANCES OF FAT AND CHOLESTEROL METABOLISM IN MAN

W Stanley Hartroft, M D
and
Wilbur A Thomas, M D, St Louis

The subject of pathological lesions related to disturbances of fat and cholesterol metabolism in man may be approached from the standpoint of systemic alterations versus local, and whether the lipid deposits are primary or secondary Despite much new information concerning atheroma obtained recently by both experimental and clinical investigations, it is still impossible to state with certainty whether this disease is primarily a systemic disorder or one of multiple local origin The most popular current concept is probably that which regards atheroma as a local manifestation in the arterial wall of a general disturbance of lipid metabolism, transport, or both

In a consideration of pathological lesions associated with abnormal deposits of stainable fat of all kinds, whether of local or systemic nature, it must be determined whether the presence of the abnormal lipid represents the initial (or primary) abnormality or whether it is merely secondary to some other injury such as thrombosis, prenecrotic degeneration, or necrosis and, thereby, only incidentally associated with a purely secondary and local disturbance of fat metabolism In which category should atheroma be placed? There are, indeed, a number of prominent investigators who feel that the deposits of lipid in atheroma may, in fact, be only secondary to other quite different initiating mechanisms, such as disorders of blood-clotting or hemorrhage

Virchow, a century ago, originally introduced the concept of fatty infiltration versus fatty degeneration characterizing the former as an accumulation of lip[illegible] in or between parenchymal cells as the morpholo[illegible] manifestation of a primary disorder of fat metabol[illegible] Fatty degeneration, on the other hand, is eith[illegible] unmasking (phanerosis) or the accumulation [illegible] in dead or dying cells, the etiology rang[illegible] simple trauma to frank infection Althou[illegible] tinction is no longer clear and simp[illegible] concept of these two types of lipid d[illegible] useful

The problem that has vexed st[illegible] for decades is concerned essenti[illegible] fications of disorders of fat m[illegible] posits of lipids in the art[illegible] manifestation of a primary [illegible]

From the Department of Pathology of Washington University Medical School fat metabolism, and is the disorder of local or systemic origin? Evidence, which cannot possibly be reviewed here, may be adduced to support almost any of the obvious combinations afforded by these categories

The arterial wall possesses certain special features known to us all and perhaps others still unrecognized The inner two-thirds or more of the wall is normally avascular and devoid of lymphatics In the cases of coronary arteries or aortas, any exudates in the wall or deposits on its inner lining will be subjected to much higher pressures than in other sites Pressure may distort the lesion so that it no longer resembles simple but perhaps quite similar alterations in other tissues, where the nature of the changes might be more readily recognized Finally, in ordinary tissue sections, contraction of the elastic and muscular web forming the media may further distort appearances With these differences borne in mind, the effects of abnormal deposits of fat and cholesterol in sites other than the vessel wall, where tissue responses are not complicated by factors unique to the latter, will be briefly reviewed For this purpose a few examples involving simple triglycerides as well as cholesterol have been chosen

Effects of Excessive Deposits of Triglycerides

In many situations, if not all, abnormal accumulation of fat within cells appears distinctly harmful both functionally and structurally One of the clearest examples may be found in the liver Rats fed a diet deficient in lipotropic factors rapidly accumulate excessive amounts of fat within the parenchymal cells of the liver When the accumulation of lipid becomes sufficiently great, the cells rupture and coalesce into fatty cysts The latter in turn serve temporarily as emergency storehouses for the extra lipid until they, in turn, rupture and their cellular remnants along with their supporting stroma condense, forming scars that become increasingly prominent as this process is repeated innumerable times These trabeculae, plus the nodularity induced by compensatory regeneration of surviving hepatic cells in other portions, eventually produce the classic picture of Laennec's cirrhosis duplicated in the animal We believe that essentially similar pathogenic sequences have been clearly demonstrated in the cirrhosis that develops in a high percentage of alcoholic patients [1]

The rat that is deficient in choline provides still another example of the effects of excessive accumulation of lipid in another organ—the kidney In the kidney the amount of lipid, estimated by either histological or biochemical methods, is never as great as in the liver The lipid accumulates in the proximal convoluted tubules of the nephrons, inducing a concomitant swelling of tubules As the latter are contained within the relatively tense capsule of the kidney, there is little room for expansion, and the capillaries between them are compressed by the swollen fatty tubules The ischemic tubules inevitably become necrotic and hemorrhagic—culminating grossly in the hemorrhagic renal syndrome of choline deficiency that was first described by Griffith and Wade [2] This sequence of events serves to illustrate another method whereby abnormal accumulation of lipid induces cellular destruction In this instance it does not result from mechanical distension and bursting of cells, as in the liver, but instead by interference with blood supply of the fatty swollen tubules that had compressed and obstructed their own nutrient capillaries

Still another mechanism by which abnormal accumulation of fat may produce or at least accompany necrosis is seen in the hearts of these young animals deficient in choline Stainable fat accumulates very rapidly within the cytoplasm and along the myofibrils The amount of fat is not sufficient to distend and burst them, nor could it be demonstrated that the lipid had directly or even indirectly induced capillary ischemia Instead, by mechanisms not apparent at present, the fatty myocardial fibers rapidly degenerated ultimately, leading to large areas of diffuse myocardial necrosis that was sufficient in some instances to produce death from myocardial failure The suggestion here is that the droplets of stainable fat interfere directly or indirectly in some unknown but catastrophic way with intracellular metabolism, perhaps involving either the mitochondria or myofibrils

In the coronary arteries of weanling rats that are deficient in choline, lipidosis develops rapidly, if the rats are older at the beginning of the experimental regimen, lipidosis develops more slowly In these arteries, the lesion resembles atheroma in many ways, but in the aorta it assumes the form of medial necrosis (Monckeberg type) Although we have seen these lesions develop in animals without appreciable renal damage, the presence of the latter definitely appears to favor the vascular changes and may be a more potent etiological factor than we initially appreciated Since our first reports from Toronto on this subject,[3] further investigations by my former colleague, George Wilgram, in Dr C H Best's laboratory have emphasized the importance of renal damage in favoring the production of this type of arterial change

Effects of Excessive Deposits of Cholesterol

Lesions associated with abnormal deposits of cholesterol in sites other than vessel walls are exemplified in the livers of animals fed cholesterol and in the various types of xanthomas such as are seen in the skin, eyelids, and tendons in man Even without histochemical procedures, the cholesterol-fatty liver can be identified The lipid is not deposited in the form of drops or globules as with triglyceride, it is usually in the form of crystals of various sizes These crystals, perhaps because of their physical form, do not fuse together into larger cytoplasmic masses displacing the nuclei as does triglyceride Instead, the crystals take up every available portion of the cytoplasm Eventually these cholesterol-loaded cells degenerate and disappear, and they are replaced by condensed stroma The hepatic lesions in animals fed cholesterol always assume their most advanced form in centrolobular positions

These cytological features of abnormal cholesterol deposits in animals' livers are consistently observed in xanthomas in man Such lesions, most frequently encountered in individuals with abnormally elevated levels of serum cholesterol, contain macrophages with centrally placed nuclei surrounded by many cholesterol crystals and needles Many xanthomas are uniquely characterized by the presence of specialized giant Touton cells, which have peripherally placed nuclei immediately beneath their limiting membranes These cells are almost pathognomonic of the lesions I have never encountered them, however, in tissues of animals fed cholesterol Fibrous tissue is the other prominent component of xanthomas, indicating that the local overloading of the tissues with cholesterol has induced cell damage with replacement by granulation tissue and scarring Ceroid or iron deposits are not demonstrable (Ceroid is a sudanophilic, amber pigment that is insoluble in fat-solvents and extractable from tissues by hot caustic alkali It was first observed in fibrous trabeculae of cirrhotic rats fed hypolipotropic diets[4])

The foregoing examples of tissue responses in man and animals in which either local or systemic alterations of lipid metabolism exist demonstrate a number of common features In every instance, abnormal deposition of either triglycerides or cholesterol, if sufficiently great, may produce irreversible forms of cell damage The actual mechanism by which necrosis develops appears to differ in various organs and sites Once cell death supervenes, there is eventual replacement by granulation tissue and scarring In the examples cited, the deposition of lipid has been regarded as the initiating event, but it must be reiterated that necrosis of cells by any agent may be accompanied by secondary accumulation of stainable fat, including cholesterol The end-result of either sequence may be identical—scarred tissue containing stainable lipids in varying quantities, so that the pathogenesis of the final lesion cannot be determined by its histological characteristics

Atheroma in Man and Animals

The difficulty of determining the significance of the histological characteristics of the lesion points up many of our difficulties in attempting to elucidate the etiology and pathogenesis of atheroma in man The histological characters of the lesions are well known, but the emphasis to be placed on their interpretation continues to be the subject of extensive discussion Holman[5] and others have demonstrated intimal and subintimal deposits of triglyceride and cholesterol, much within macrophages or so-called foam cells in very small atheromatous lesions in man Paterson[6] has detected stainable iron in these small lesions, and one of us[7] has reported the presence of traces of ceroid pigment in small atheromas There is considerable agreement between all observers, however, that, whatever its etiology, the lesion is initially one of intimal and subintimal tissues Medial involvement and changes in elastic and muscle tissue are undoubtedly secondary

Atheroma in man is characterized by a change in the inner wall of the artery accompanied by intimal thickening, presence of triglyceride, cholesterol, iron, and ceroid deposits, fibroblasts, macrophages, and capillaries The latter three elements are covered by the term granulation tissue In old lesions, granulation tissue has progressed to frank fibrosis Deposition of masses of calcium salts and ulceration are only observed as secondary and late complications, and in these instances medial necrosis and fibrosis may be seen Because of the emphasis currently placed on the lipid components of atheroma, their nature will be considered further

It can be demonstrated histochemically, even in early lesions, that cholesterol and cholesterol esters are prominent from the start Triglyceride and ceroid, however, are almost equally abundant These features can be illustrated by comparing photomicrographs of the same region of the atheromatous arterial wall illuminated with and without polarized light, and before and after extraction with alcohol and xylol These observations suggest that all three types of lipid may be present in nearly equal proportions Many investigators, however, feel that cholesterol is the first lipid to be deposited in any appreciable amount and that the others follow Further evidence to support this view is needed before it can be universally accepted in the case of man

Recently, Tuna[8] and his associates at the University of Minnesota have subjected the lipids in circulating plasma obtained from normal subjects to a careful and exacting biochemical scrutiny Parallel observations were made on lipids extracted from human atheromatous plaques With their very advanced techniques, they were able to identify many of the fatty acids of the triglycerides and cholesterol esters obtained from both sources and to arrive at quantitative comparisons They failed to demonstrate any significant difference quantitatively or qualitatively between the composition of the fatty acid fractions in normal plasma and atheromatous plaques No differences in relative solubilities of comparable fractions of either samples existed Their results together with our histochemical studies, therefore, indicate to us that ceroid deposits are the only lipids, albeit pathological, in atheromatous plaques that differ significantly from those of serum The striking feature of ceroid, which can be roughly compared to an oil paint, is its insoluble nature Once formed it may contribute significantly to the development of irreversible tissue responses in the arterial wall We have already demonstrated the sclerotic action of ceroid in canine aortas by injecting the substance, which was artificially prepared from canine red blood cells and unsaturated fat incubated in vitro at body temperature for several days, into the vessel wall at laparotomy When the animals were killed two to four weeks later, fibrosis was apparent around the injected ceroid Fibrosis was not found in the aortas of control animals similarly injected with triglyceride We are currently investigating further this approach to the pathogenesis of atheroma

Cholesterol has been used successfully to produce in experimental animals arterial lesions that have many resemblances to atheroma in man Feeding large amounts of cholesterol to rabbits will produce vascular changes The pathogenesis of these lesions has been studied intensively, the late Dr G Lyman Duff and colleagues,[9] employing ingenious techniques, have elucidated their development in a particularly helpful fashion They discovered that both triglyceride and cholesterol appear within the aortic endothelium and beneath it within a few days after the initiation of the experimental regimen. Later, the intima is heaped up by massive deposits of cholesterol and triglyceride, contained chiefly by foam cells beneath the endothelial lining. Unlike aortic atheroma in man, these lesions are more numerous in the arch and thoracic portions of the aorta rather than in the abdominal segment. This difference in distribution also holds for cholesterol-induced lesions in rats fed thiouracil, as in Wissler and associates' experiments[10] and those reported by Stare and co-workers,[11] who used somewhat similar dietary regimens. The aortic lesions induced in rats deficient in choline, already mentioned, are also more numerous in the thoracic than in the abdominal regions of the aorta.

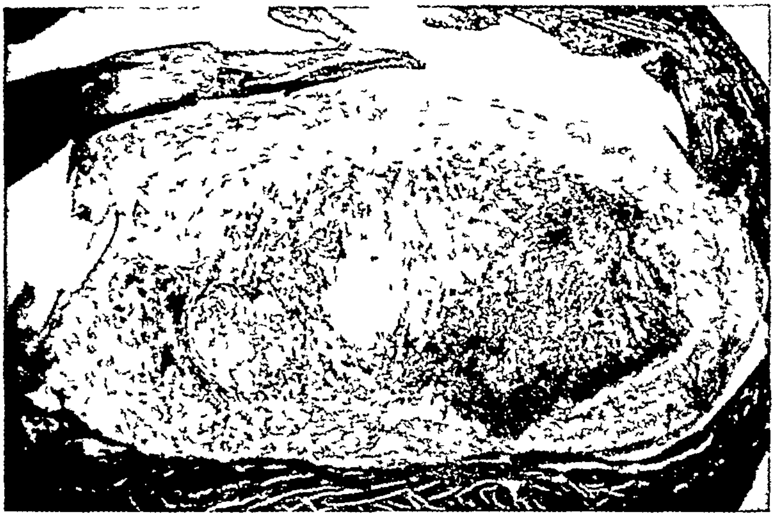

Fig. 1.—Section from apex of rat's heart with myocardial infarct and large mural thrombus. Fat appears black. Oil red O stain on frozen section.

With the exception of the type of vascular damage induced by a deficiency of choline, cholesterol alone or in other combinations has been used to produce atheromatous lesions in almost all experiments reported to date. Stare and Mann[12] employed cholesterol in combination with diets deficient in methionine to produce coronary and aortic lipidosis with intimal proliferation in Cebus monkeys. Thiouracil, as already mentioned, is apparently a necessary adjunct in the case of the rat and dog. Chickens and rabbits, the former extensively studied by Katz and associates,[13] appear to be the only species in which atheromatous changes can be produced readily at will by feeding cholesterol alone.

The late Dr. Reinhart[14] was able to produce aortic lesions in monkeys closely resembling human atheroma by feeding the animals diets deficient in pyridoxine. These experiments have recently been confirmed in both monkeys and dogs deficient in pyridoxine.[15] Lipid is apparently not deposited in these lesions under the experimental conditions employed. In addition to these and other differences between atheroma thus far produced in experimental animals and that in man, ceroid deposits have not been found in the former. We have searched vascular lesions produced in rats and rabbits by a variety of techniques and have failed to demonstrate the presence of ceroid. One of the most important differences between the production of atheroma in experimental animals and that found in man, is the absence, aside from a few scattered instances, of the regular production of important complications such as myocardial infarction in any series reported.

Experiments initiated by Duguid,[16] Harrison,[17] and others and extended by one of us and co-workers[18] have conclusively demonstrated that injection of thrombi into rabbits' ear veins will produce morphologic counterparts of atheroma in their lungs that are the end-results of organization of the thromboemboli trapped in small pulmonic arteries. Meals with high fat content were fed to clot-injected rabbits by means of stomach tubes. A standard dose of injected clot produced more lesions in the animals fed fat than in control animals similarly injected but fed water or syrup instead of fat. Of the various fats tested, butter was most efficacious in this regard, whereas corn oil had no effect. A sequence of morphologic changes can be traced in man that indicates the probable transformation of organized thromboemboli in pulmonic arteries to lesions that all would term pulmonic atheroma.

The real reason, of course, for such vital interest in atheroma is that myocardial infarction is the frequent and fatal complication of coronary atheromata. Evidence accruing from the epidemiologic studies of Holman and McGill[19] and one of us and others[20] has led some of us to suspect that the factors that

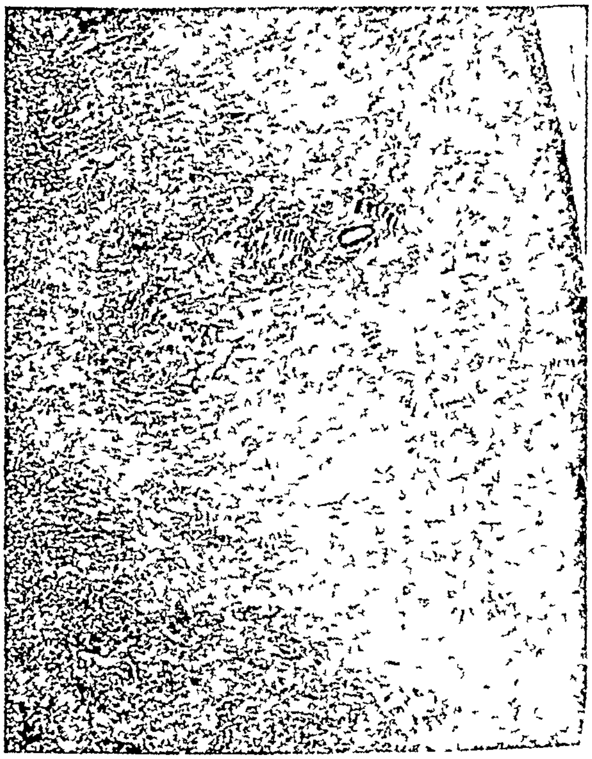

Fig. 2.—Large renal infarct in rat's kidney. Hematoxylin and eosin stain on paraffin section.

initiate atheroma may not necessarily be identical with those responsible for its fatal complications Aside from a few reports of the sporadic occurrence of isolated cases of myocardial infarction in experimental animals, there are to date no published methods for producing at will cardiac infarction in intact animals On several occasions,[21] we have previously emphasized the need for such an experimental model so that any factors responsible for myocardial infarction, as distinct from atherogenic mechanisms, can be studied adequately Stimulated by a recent report from Dr Stare's laboratory of one case of myocardial infarction in a rat in one of his experiments and by some encouraging preliminary experiments of our own, we have been attempting for the past year to produce myocardial infarction in rats by purely dietary measures We believe that we have met with a sufficient measure of success to warrant reporting the progress of these experiments at the present time Wilgram[22] has recently reported the development of 'numerous areas of old and recent cardiac infarcts' in the hearts of two rats fed diets containing cholesterol, cholic acid, propylthiouracil, and large doses of Viosterol His results accord with those reported above

Dietary Induction of Myocardial Infarction in Rats

Male albino rats of the Wistar strain (initial weights of 110 Gm) were fed diets containing high levels of various types of fat (40% butter, lard, or hydrogenated fat) supplemented with cholesterol, cholic acid, and thiouracil in order to elevate the animals' serum cholesterol levels (Details of the experimental procedure will be reported elsewhere in a paper now in preparation for publication) The protein content of the diets varied in the different groups from 12 to 20%, and a supplement of 1% choline chloride was added in some instances Our results have not progressed sufficiently far for us to evaluate the relative importance of these various factors in the production of myocardial infarction In the animals fed diets containing high amounts of saturated fat (butter or lard) for 14 weeks, we have encountered extensive myocardial infarction with formation of mural thrombi (fig 1) in incidences ranging from one animal in nine to as high as five of nine (the latter on a diet containing 12% protein and 40% lard) Renal infarcts (fig 2) were also encountered in many of these rats The cardiac infarcts were most frequently observed at the apices and margins of the left ventricles (fig 3) Necrosis is most extensive in the inner portions of the wall, sparing to some extent the subepicardial regions The thrombi within the left ventricle were attached to the infarcted apex and in some instances filled the left ventricular cavity nearly completely Stainable fat consisting of both cholesterol and triglyceride is present in the infarcted muscle but is absent in the adjacent nonnecrotic regions (fig 4) Ceroid deposits have been demonstrated in considerable abundance within the thrombi, where more soluble lipids can also be found Thrombi were demonstrated in coronary arteries supplying the infarcted regions of myocardium (serial sections)

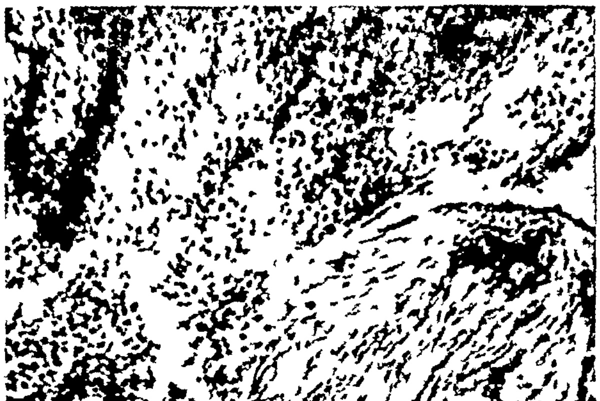

Fig 3 —Infarcted myocardium and mural thrombus in section of rat's heart Oil red O stain on frozen section

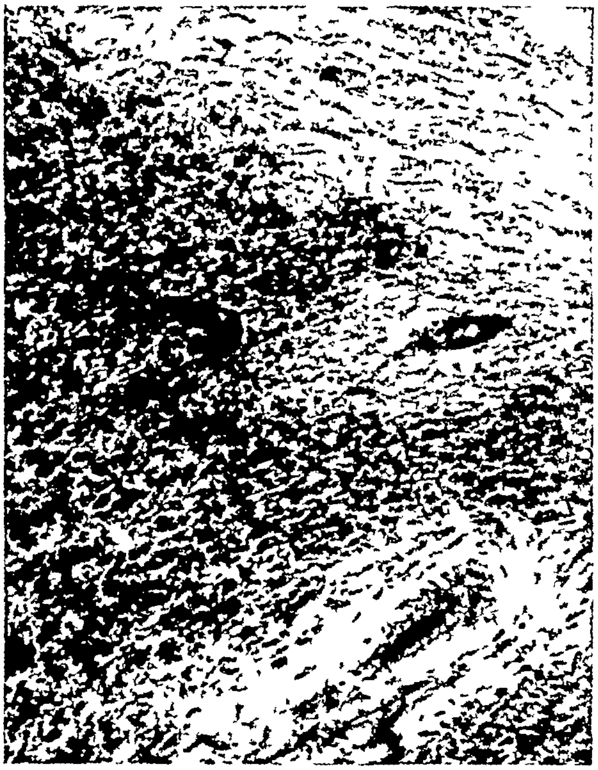

Fig 4 —Portion of infarcted myocardium from rat showing large quantities of fat in dead muscle and none in adjacent living muscle Oil red O stain on frozen section

We believe that these animals developed myocardial infarcts because factors that raised the levels of blood cholesterol and a high supplement of saturated fat

(40% butter or lard) were combined in the same dietary regimen In order to evaluate properly the relative importance of these factors, however, more experiments are needed, some of these are already underway in our laboratory Now that we have produced what seems to be a significant incidence of the lesion, it should not be difficult to test the effects of various dietary situations along with other factors such as age, sex, and diabetes on the incidence of myocardial infarction in rats under these conditions We hope by this approach to elucidate some of the interrelations between known atherogenic mechanisms and those actually responsible for the fatal complications of atheroma Should we achieve our objective, it might prove possible to learn how to prevent the complications of atheroma, if not to reverse the actual lesions, thereby perhaps permitting those of us with narrow coronary arteries to live with them

Summary

A study of pathological changes related to disturbances of fat and cholesterol metabolism as manifested in a variety of sites such as in the liver, kidney, heart, skin, and tendon in both animals and man indicates that the lesions in all these situations have a number of features in common The cells laden with lipids eventually degenerate and disintegrate, to be replaced by granulation tissue and eventual scar formation Cytological details vary with the type of lipid (triglyceride or cholesterol), and considerable differences are encountered in the pathological pictures at different stages of these lesions In various sites, the mechanisms differ by which the local overload of the tissues with lipid results in cellular death Both triglyceride and cholesterol deposits not only may initiate tissue necrosis but also may be the result of the latter Eventually, the pathological changes in both instances, whether the lipid deposits are primary or merely a secondary sequence, may be so comparable that the pathogenesis in any instance is impossible to determine from the end-result

At least three types of lipid are prominent in even small lesions of human atheroma Cholesterol deposits are accompanied by almost equally abundant amounts of triglyceride and ceroid in the regions of the affected intima As the lesions progress, granulation tissue and scarring develop beneath the intima, and later gross calcification, ulceration, and medial degeneration may supervene Atheroma is primarily a disease of the inner layers of the arteries, and this fact is at present generally accepted Evidence to date indicates that ceroid is the only lipid constituent of the arterial plaques that differs in any significant degree from lipid circulating in the plasma Ceroid, probably virtually absent from the circulating blood, is characterized most significantly by its high degree of relative insolubility in either aqueous or organic solvents Many types of experimental atheromas produced in animals do not contain ceroid deposits of the type found regularly in typical lesions in man

Up to the time of writing, it has not been possible to determine by animal experiments the relative importance of various factors in initiating atheroma as compared with their possible roles in the development of its fatal and important complications, notably myocardial infarction To carry out such studies, it is necessary to develop an experimental model in which myocardial infarction can be produced at will in a significant percentage of the animals We have reported experiments in which we believe this objective may have been achieved, at least in part, by the production of myocardial infarction in rats fed diets high in cholesterol and saturated fats for 14 weeks Evaluation of the relative importance of some of the dietary procedures that were employed awaits the results of further experiments

Atheroma may be the result of a primary disturbance of fat and cholesterol metabolism in man, but morphologic evidence has not established whether the lipid deposits are primary initiating events or secondary sequelae in the pathogenesis of the lesions It remains to be established whether the lipid disorder, even if primary, is a local disturbance in the arterial wall or a focal manifestation of a systemic alteration of fat metabolism or transport Until specific answers to these and other questions raised in the foregoing are obtained, it is likely that myocardial infarction will continue to be the most important single cause of death in the American population

DIETARY CONTROL OF SERUM LIPIDS IN RELATION TO ATHEROSCLEROSIS

Edward H Ahrens Jr, M D, Jules Hirsch, M D, William Insull Jr, M D,
Theodore T Tsaltas, M D, Rolf Blomstrand, M D
and
Malcolm L Peterson, M D, New York

There is a serious lack of direct evidence that atherosclerosis is due to alterations in fat metabolism Yet, the hypothesis is made attractive by various lines of reasoning—pathological, clinical, and epidemiologic In its simplest form (fig 1), the postulate states that some peculiarity of dietary fat leads to abnormalities in serum lipids that cause an accumulation of fat in blood vessel walls Over many years the narrowing of certain vital vessels produces no recognizable disability until complete occlusion, often abetted by thrombosis, results in a sudden vascular accident This occurrence is usually late in a long sequence of events Many patients show massive degrees of atheromatosis at autopsy without having had clinical signs of coronary vessel involvement, conversely, some patients die of myocardial infarction secondary to a small localized coronary occlusion but show little generalized atheromatosis Obviously many factors must be important at various stages in the genesis of this disease, such as local anatomic peculiarities, hemodynamic factors, clotting, genetic traits, and endocrine relationships However, the line of reasoning to be considered here invokes a disorder of lipid metabolism

Evaluation of the Hypothesis

Historically, the theory that there is a relationship between diet and myocardial infarction had its beginning when it was demonstrated that cholesterol is present in atheromas and when Anitschkow produced atheromatosis in rabbits by feeding cholesterol In these animals it was clear that a dietary factor caused hypercholesteremia and in turn atheromatosis However, the importance to be attached to these observations must be weighed against other considerations

1 Rabbits are herbivorous and may not have effective mechanisms for metabolizing an animal sterol with the same dispatch as omnivorous animals

2 It is difficult to produce the same sequence of events in rats unless large amounts of bile acids are also fed, or in dogs unless the thyroid is simultaneously blocked, or in monkeys unless cholesterol, bile acids, and an incomplete protein are given together

3 The atheromas produced by feeding cholesterol to animals show important differences in character and in distribution from human lesions Moreover, there is a generalized cholesterosis involving the liver, spleen, and bone marrow in the animal that is fed cholesterol but not in the atheromatous man

4 Coronary occlusions with myocardial infarction have rarely been reported in experimental animals with severe atheromatosis, until the announcement by Drs Hartroft and Thomas in this symposium Their production of myocardial infarction in rats represents a very important advance Nevertheless, these animals were challenged with every weapon at the experimenter's disposal deficiency of protein and choline, administration of cholesterol and bile acids, medical ablation of the thyroid, and a diet high in saturated fats This exciting development serves to focus our attention on the puzzling fact that, whereas atheromatosis in animals is easily produced, myocardial infarction can be simulated only with great difficulty and by means that have no counterpart in human nutrition and metabolism Although observations made in the laboratory in the last 40 years have had an exceedingly stimulating effect on research in this field, present opinion seriously qualifies the direct relationship between dietary cholesterol and atherogenesis in man

The second major basis for the hypothesis involves the high incidence of arteriosclerotic disease in patients who manifest hypercholesteremia It is frequently claimed that patients with myxedema and nephrosis have severe atheromatosis at autopsy, however, these entities are rarely complicated by myocardial infarction Because diabetes and familial hypercholesteremia are both genetically determined, it can be questioned whether atheromatosis that develops in persons with

---

From the Rockefeller Institute, New York Dr Tsaltas is now with the New York University College of Medicine Dr Blomstrand is now with the University of Lund, Lund, Sweden these conditions is caused by abnormal lipid metabolism as the primary defect Is it not worth considering that in these groups hypercholesteremia and arteriosclerosis may both be genetically determined and that the two manifestations of disease need not be causally related? Wilkinson studied many members of a familial group with hypercholesteremia and found no greater incidence of coronary disease in the members who had hypercholesteremia than in those whose serum cholesterol values were normal[1]

The third major line of evidence favoring the sequence shown in figure 1 rests on data gathered in various parts of the world by Keys and his co-workers[2] Their data illustrate a relationship between total intake of dietary fat, serum cholesterol levels, and incidence of arteriosclerotic heart disease Exercise, economic status, stress of living, and obesity are stated to play no primary role in this process A number of criticisms of the validity of these data have been summarized recently by Page and associates[3]

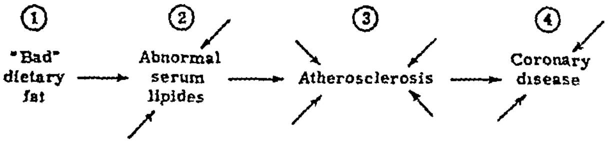

Fig 1 —Postulated relationship between diet and myocardial infarction Additional arrows signify other factors

To us, the most serious weakness of this type of evidence lies in our inability at the present time to quantitate the extent of the atheromatous process during life (fig 1, part 3) Not only does this weak link prevent an evaluation of the extent of the disease process in relation to abnormal serum lipids and antecedent dietary malpractice, but it also prevents the direct estimation of the effectiveness of any regimen that might ameliorate the process It is regrettable that the good and bad features of any environmental factor cannot be evaluated except in terms of the complications of the atherosclerotic process (fig 1, part 4)

It is entirely possible that the scheme shown in figure 1 will be proved correct when further facts have been gathered through new approaches to the problem However, when unproved hypotheses are enthusiastically proclaimed as facts, it is timely to reflect on the possibility that other explanations can be given for the phenomena observed Let us postulate that another factor, X, is responsible for atherogenesis Under certain modifying circumstances X also causes abnormal serum lipid states X might be pyridoxine deficiency, this vitamin acts as a coenzyme in fatty acid metabolism[4] It might be a trace metal affecting cholesterol synthesis,[5] or a bulk-former in the diet, which might influence intestinal micro-organisms and in turn the excretion of fats and sterols X may be a factor as yet unnamed The importance of recognizing this possibility lies in the fact that experiments, clinical or epidemiologic, cannot be planned with adequate control of X if X is unknown

These introductory remarks have been made in considerable detail in order to underline the uncertainties that the clinician faces when he debates whether to prescribe a change in dietary regimen for his patients as a preventive measure against arteriosclerosis and coronary disease As a scientist, he will preserve some degree of skepticism when claims are made for the efficacy of certain foods and the evils of others, knowing how difficult is the hurdle from 2 to 4 in figure 1, not to mention that from 1 to 4 However, in patients with coronary disease he may be justified in applying an unproved hypothesis, if it can be shown that certain changes in dietary habits produce definite alterations in the concentrations of serum lipids

Alterations of Serum Lipids in Man by Changes in Diet

In 1952 Kinsell and co-workers[6] published clinical experiments indicating that the replacement of animal fats with vegetable fats resulted in dramatic decreases in concentrations of cholesterol and phospholipids in the serum During the same year, Groen and co workers[7] showed that the ingestion of a vegetarian diet produced a significant depression of serum cholesterol levels Then, in 1954, Hardinge and Stare[8] reported a study of vegetarians in which it was shown that serum cholesterol levels were lower in those who ate no dairy products than in others who ate eggs and milk as well as vegetables

Kinsell's important reports were confirmed by our group[9] in 1954 in experiments on six obese but otherwise normal patients Comparable results were obtained in a seventh patient, 49-year-old male with hypercholesteremia who had skin and tendon xanthomatosis, whom we studied for 22 weeks (fig 2) His weight was held constant by administration of adequate calories His food intake was derived largely from natural mixed cooked foods but in part from a

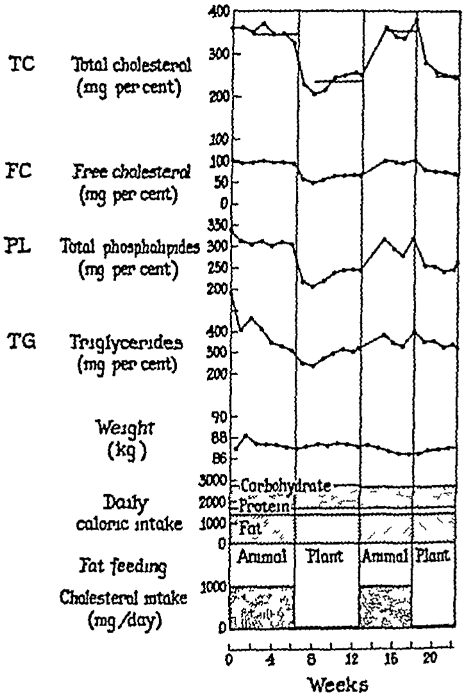

Fig 2 —Twenty-two-week study of serum lipids of 49 year old male with hypercholesteremia who had skin and tendon xanthomatosis and history of cerebral vascular accident and coronary occlusion Isocaloric exchange of plant and animal fats in the diet

liquid homogenate of fat and protein, as described previously[9] The metabolic mixture of his food intake represented that of a well-fed American 12% protein, 50% fat, and 38% carbohydrate In four study periods, his dietary fat intake alternated isocalorically between animal and vegetable fats His cholesterol and phospholipid levels decreased in the two periods in which vegetable fat was ingested and stabilized at the same higher levels in the two periods during which he was given animal fats

Effects of Individual Fats

Since it has become clear that differences can be produced in human serum lipid levels by substitution of one dietary fat mixture for another, further understanding of the process has been sought by study of the effects in man of ingestion of individual fats of widely varying composition Body weight must be held constant in such experiments because lipid levels rise or fall in the serum when weight is gained or lost respectively Other variables that might influence serum lipid levels, such as psychic unrest, metabolic fluctuations, exercise, infection, and endocrine therapy also must be minimized

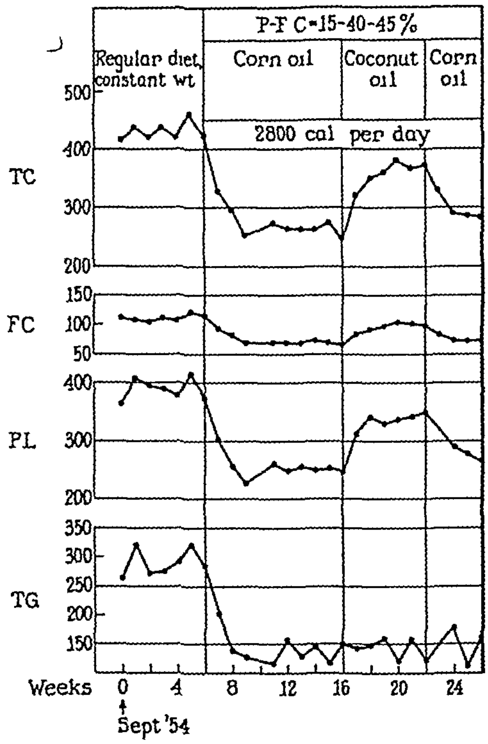

Fig 3 —Twenty-six-week study of serum lipids in 27-year-old male with hypercholesteremia without apparent vascular disease or xanthomatosis For lipid abbreviations on vertical axis, see fig 2 P-F-C=protein, fat, carbohydrate intakes, as percentage of total calories Note 3 week transition periods after each dietary exchange before levels became steady

An experimental technique was developed[10] for the preparation, storage, and dispensing of homogenized mixtures of milk protein, carbohydrates, and single test fats It has the advantage of rigid control of all intakes and eliminates the undefined effects of cooking These mixtures were administered by mouth as the sole source of nutrients Daily supplements of iodized salt, iron, and a multivitamin mixture were given Details of this regimen have been fully described[10] Patients were carefully selected for minimum study periods of 4 months They were purposely not a homogeneous group, but included males and females from 13 to 72 years of age Some were normocholesteremic and others hypercholesteremic They had no manifest infectious or endocrine disease, and all were ambulatory Many of the patients had coronary insufficiency and a distant history of myocardial infarction, but none was in cardiac failure A few patients with hypercholesteremia or hyperlipemia had no evidence of vascular disease Forty-one of the 43 patients were hospitalized on a metabolic ward for their 4-month to 36-month studies They were maintained on oral formula feeding throughout these periods without recognized ill-effect At six-week intervals or longer, as circumstances demanded, exchanges of formulas were made in which one fat was isocalorically substituted for another In this manner more than 25 fats have been tested The results of these experiments are described in detail elsewhere[11]

These experiments have shown that some dietary fats produce higher serum cholesterol and phospholipid levels than others but that the triglycerides in the serum are relatively constant and do not vary in parallel with the other lipid groups The highest levels of cholesterol are found when butter and coconut oil are fed as sole dietary fats, intermediate levels are produced by palm oil, lard, cocoa butter, and olive oil, the lowest levels follow the feeding of peanut, cottonseed, corn, and safflower oils A linear correlation was found between the degree of saturation of the dietary fat and the levels of cholesterol and phospholipids in the serum Statistical analysis indicated that results are best correlated with the mean degree of saturation of the fat (as measured by its iodine value) There was no better correlation with its content of

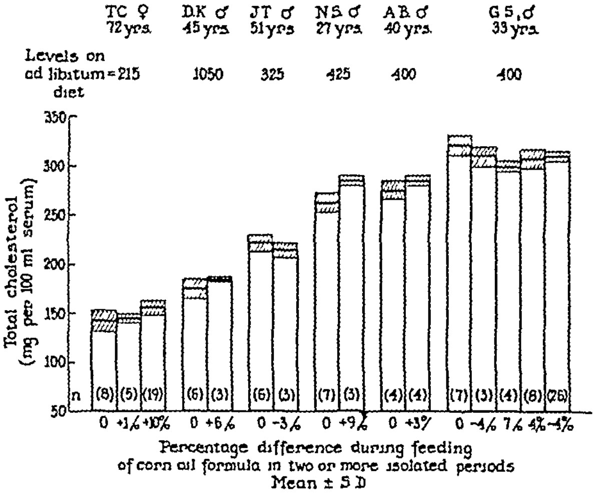

Fig 4 —Reproducibility of serum cholesterol levels in 6 patients retested on basic corn oil formula (P-F-C=15-40-45% of calories), with other regimens in intervening periods Bars show mean levels during steady states, hatched areas=one standard deviation, n=number of weekly data during each steady state Percentage differences along baseline calculated with reference to mean levels of first feeding periods

any specific fatty acid, such as linoleic acid Tests with fats that had been treated to remove a large part of the minor components (the nonsaponifiable materials) showed no loss of effectiveness in reducing cholesterol levels On the other hand, hydrogenation of the highly unsaturated fats vitiated the effect of these fats in lowering the cholesterol level These data are consistent with but do not prove the hypothesis that the ingestion of unsaturated fats leads to lowered levels of cholesterol and phospholipids in the serum A mechanism for this effect has been suggested[12]

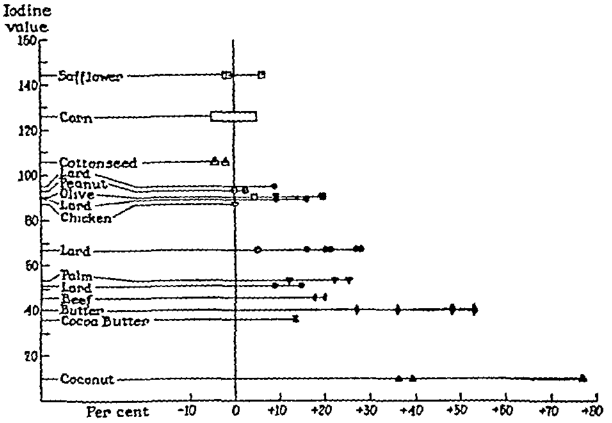

Fig 5 —Relationship between iodine values of dietary fats and serum cholesterol levels expressed as percentage differences from baselines established during ingestion of corn oil iodine values of fats listed along vertical axis Open bar at iodine value 126=estimated reproducibility of corn oil baseline (fig 4) Open symbols represent results not significantly different from baseline, solid symbols different at level of $p<0.01$ hatched symbols different at level of $p<0.05$

Experiments that substantiate these statements are shown in figures 3 to 7 Figure 3 demonstrates that a saturated fat, coconut oil, causes higher lipid levels than an unsaturated oil, corn oil When corn oil formula is fed repeatedly to the same patient, other feeding periods intervening, the same cholesterol levels are achieved within ± 5% (fig 4) As all patients do not respond to corn oil to the same degree, the serum lipid levels achieved during ingestion of the corn oil formula can be used as control values for each patient and the percentage differences between control levels and those produced by other dietary fats can be calculated When these percentage differences are related to the iodine values of the various fats tested, a linear relationship is obtained (fig 5)

The percentage difference in cholesterol levels between corn oil and other test fats can be related to the fatty acid composition of the fats by the formula $P=0.14\ L-0.49\ I+47$, where P=percentage difference, L=contribution of linoleic acid to the total iodine value of the fat (or linoleic acid content×1.8), and I=total iodine value of the fat If the L expression is omitted entirely, the formula becomes $P=-0.37\ I+44$, and the fit of the data to this simplified calculation is just as good as with the longer formula (F test) Since P can be so well equated with iodine value, the calculation shows that the effect of dietary fats on serum cholesterol levels is perhaps more a function of mean unsaturation of the fat rather than of the content of any specific acid, such as linoleic acid Even oleic acid, which is not an essential acid, thus makes a sizable contribution This is verified by the fact that olive oil, rich in oleic but poor in linoleic acid, produces almost as great depression of serum cholesterol as does peanut oil, which is rich in linoleic acid The statistics and their interpretation are discussed more fully elsewhere[13]

It is obvious from the data presented in figure 4 that no formula can be expected to predict serum cholesterol levels of all patients from knowledge of the composition of their dietary fat, except possibly when applied to a homogeneous group of normo cholesteremic subjects On the other hand, our formulas show that in any patient the response to two dietary fats can be related to each other in terms of their two fatty acid compositions Although these calculations have no practical value for the clinician, they offer some insight into the mechanisms involved by demonstrating that the phenomena we are studying are likely due to differences in fatty acid compositions of dietary fats

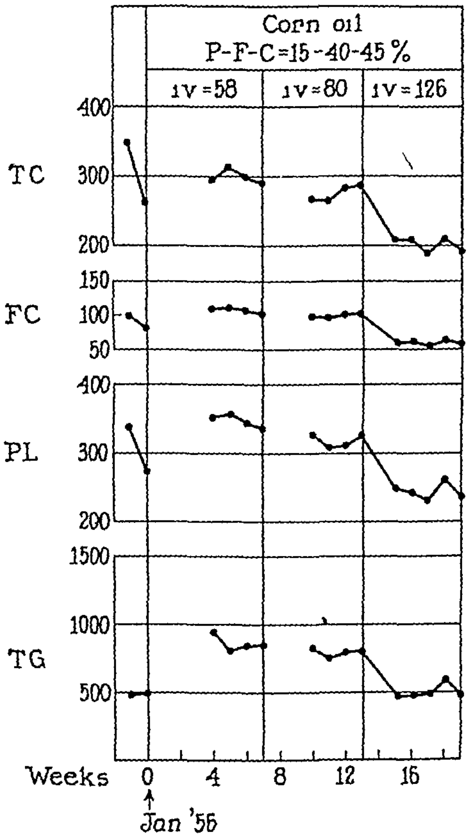

Fig 6 —Effect of ingestion of corn oil hydrogenated to iodine values of 58 and 80 compared to unhydrogenated oil Levels of TC and PL significantly different ($p<0.01$) in all 3 test periods Fifty-year-old male with history of myocardial infarction

The ingestion of formulas containing corn oils saturated by hydrogenation to iodine values of 80 and 58 produced successively higher levels of cholesterol and phospholipids in the serum (fig 6), and the removal of 80% of the nonsaponifiable materials such as sitosterols, carotenes, and tocopherols, from corn oil failed to abolish its cholesterol-lowering properties (fig 7)

These experiments do not prove conclusively that saturated fats elevate and unsaturated fats depress serum cholesterol and phospholipid levels, although the data are entirely consistent with this hypothesis The experiments so far accomplished have utilized processed natural fats, all containing significant amounts of nonsaponifiable material that in trace amounts might account for the effects observed Long-term tests must be carried out with highly purified synthetic glycerides in order to substantiate the conclusion, now presumptive, that the described effects on serum lipids are caused by the fatty acid composition of ingested fats

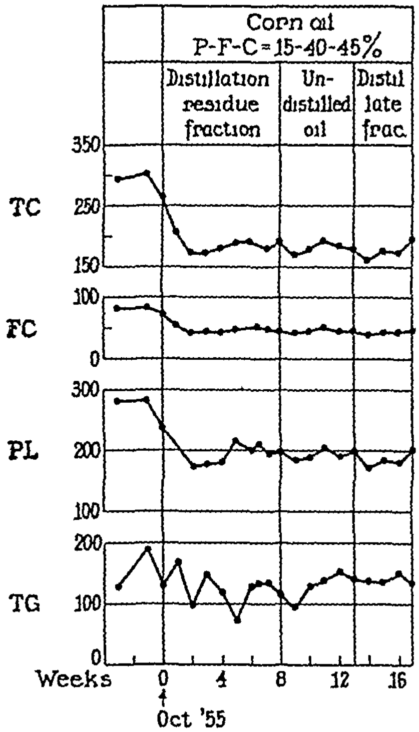

Fig 7 —Lack of dietary effect on serum lipids of 6 fold difference in nonsaponifiables of corn oil Molecular distillation enriches nonsaponifiables in distillate fraction, residue fraction is poor in this material Sixty-seven-year old male with history of coronary insufficiency

Effects of Variations in Fat Intake

In all experiments with formula feeding summarized previously, dietary fat comprised 40% of the total calories If the proportion of fat calories were less than 40%, would levels of serum lipids be decreased? Figure 8 demonstrates that, when corn oil made up only 10% of total calories, there was a sudden marked increase in serum triglyceride levels as well as a small rise in phospholipid and cholesterol levels When the corn oil intake was increased to 70% of total calories, there was a prompt fall in triglyceride and other lipid levels Thus the lowest serum lipid levels occurred on the highest intake of corn oil

Similar changes have been produced in four other patients In the oldest of these, a 72-year-old female with coronary insufficiency, there was a four-fold increase in the serum triglyceride level when a formula containing 70% of calories from corn oil was replaced by a diet free of fat [13] In addition, there was marked lipemia on the fat-free diet and a striking increase in $S_f >$ 20 lipoproteins It remains to be determined whether this response is a function of age, less dramatic effects on triglycerides were produced by these dietary alterations in a 33-year-old hypercholesteremic male Hatch and associates [14] also noted a rise in the triglyceride level and abnormal ultracentrifugal patterns in patients fed rice diets low in fat

Such experiments demonstrate that the various serum lipid levels need not vary in a parallel manner and that a total cholesterol value may give little indication of the other lipid levels Since in some patients a diet low in fat produces high levels of serum triglycerides, we are tempted to ask whether the lower-density lipoproteins are less 'atherogenic than the higher-density lipoproteins rich in cholesterol and phospholipids We know of no solid evidence on this point, and until the question is further explored we question the wisdom of prescribing low-fat diets for the general population

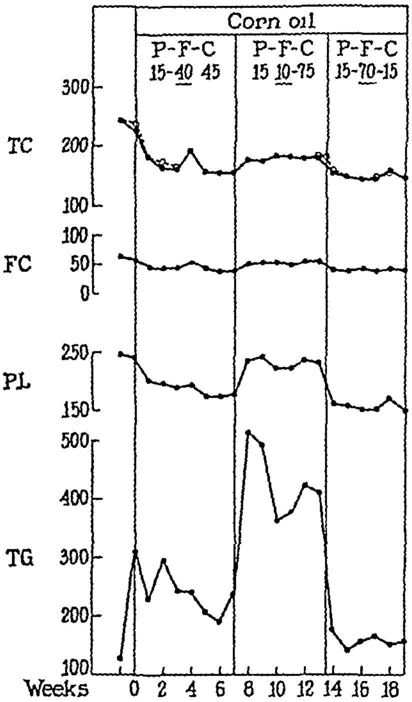

Fig 8 —Effect on serum lipids of varying the proportions of fat and carbohydrate calories reciprocally, keeping total calories, protein, and body weight constant Major changes produced in serum triglycerides, smaller effects on phospholipids, least striking differences in cholesterol Lowest serum lipid levels on highest intake of corn oil Fifty-three-year-old male with history of coronary insufficiency

Effects of Vegetarian Diets

Figure 2 shows the effects on serum lipid levels of diets that consisted in part of liquid homogenates It was desired to compare more strictly the effects of ingestion of animal and vegetable fats, isocalorically exchanged but derived entirely from natural solid foods without supplementation by liquid homogenates. Figure 9 presents an experiment in a 60-year-old male with coronary insufficiency, who was fed a metabolic mixture in which 15% of the calories were derived from protein, 40% from fat, and 45% from carbohydrate. In the first period his entire food intake consisted of the basic corn oil formula already discussed. In the second and third periods his food was derived entirely from natural mixed solids. All fat was of vegetable origin in the second period and of animal origin in the third period. It is clear that levels of cholesterol and phospholipids were lower in the vegetable than in the animal fat period.

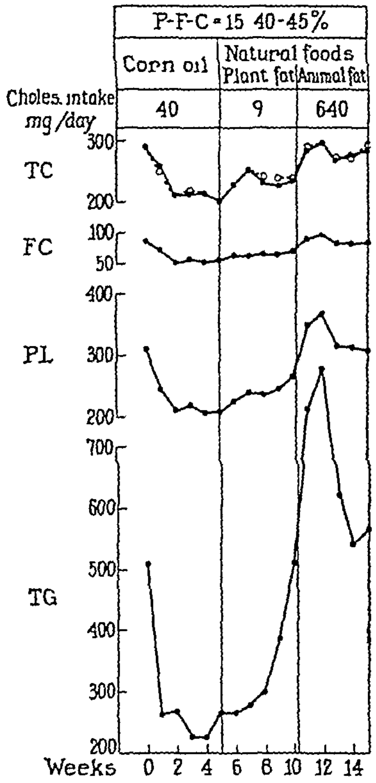

Fig 9.—Effects on serum lipids of corn oil formula compared to two diets of natural mixed solids, with all fat of vegetable origin in second period all of animal origin in third period. Mixture of fat, protein, and carbohydrate held constant in all feedings. Note delayed triglyceride response in second period. Sixty one-year-old male with history of myocardial infarction.

In view of this experiment and those previously cited, it seemed advisable to evaluate the effects of total vegetarianism on serum lipids in a study of outpatients. All meats, poultry, fish, and dairy products were omitted, except for washed cottage cheese and skim milk. Oleomargarine (3 to 4 pats per day) was given to replace butter. The table shows the results of this dietary management of eight patients in whom lipid patterns also were determined when ad libitum diets were ingested. In all cases the levels were lower on the vegetarian regimen. When their nourishment was derived from liquid homogenates containing corn oil at 40% of calories, their serum cholesterol levels were still lower.

Practical Measures for Control of Serum Lipids

Experience to date has shown that two regimens are effective in lowering serum lipid levels of our outpatients. The first is total vegetarianism, in which all dairy products are omitted except for skim milk, washed cottage cheese, skim milk cheeses and egg whites. This regimen has been no less effective, in terms of serum lipids, when supplemented with fish and shellfish once or twice daily. Soybean recipes, olives, nuts, and avocados can be used to advantage. Oriental and near Eastern dishes have proved to be appealing and offer variety to a diet that relies heavily on fruits, vegetables, starchy foods, and nuts. This first regimen is difficult for patients who eat many meals in restaurants.

The second regimen consists of a very low fat diet (less than 25 Gm. per day) supplemented by an ounce or more of corn oil at least three times daily. Our goal has been to achieve maximum dietary effects on serum lipids, and very high intakes of the unsaturated fats have been required. The basic diet offers modest portions of lean meats, chicken, and fish each day. Many recipe books that help to make a low-fat regimen acceptable have been published.

Indications for Dietary Management

It is clear that serum lipid levels can be influenced by dietary manipulations. The findings presented in this paper are entirely consistent with the observations made by Kinsell and Michaels,[15] Bronte-Stewart and associates,[16] and Beveridge and associates.[17] Although considerable progress is being made in defining those elements in the diet that produce such changes, much remains to be learned about the effects of many nutritional ingredients. Indeed, the mechanism of the changes caused by dietary fats has only recently been studied.[18] The data in a single patient have indicated that excretion of cholesterol is affected and that serum

cholesterol is not retained in some other tissue when its concentration is made to decrease by dietary means We firmly believe that the answers to these and other important questions will be available in the next few years

In view of the fact that it has not been demonstrated in man that lowered levels of serum lipids will alter his susceptibility to atherosclerosis and in view of the many questions that remain unanswered in this year 1957, it seems inadvisable at this time to recommend that the general public eat more or less fat or avoid fat of any particular type We believe that much more basic information should be gathered before widespread changes in dietary habits are adopted It is entirely probable that this period of indecision will be short-lived, since progress is rapidly being made in fundamental areas of lipid biochemistry and nutrition

On the other hand, where the likelihood of death or disability from atherosclerosis is great—in patients with a personal or family history of the complications of arteriosclerosis and in those with hypercholesteremia—it is reasonable to act on an unproved hypothesis if the risk of so doing is small It seems justified in such cases to recommend dietary measures that depress levels of serum lipids We have presented two regimens that furnish large amounts of unsaturated fats at the expense of saturated fats and carbohydrates The maximum effect on serum lipids may not be achieved in hypercholesteremic patients for as long as eight weeks Applying these diets, it has been gratifying to observe the disappearance of skin xanthomas in patients with hypercholesteremia or with hyperlipemia Many of our patients with coronary insufficiency have experienced considerable improvement in angina However, our follow-up periods have been short (four months to three years), and it seems likely that their symptomatic improvement is the result of reassurance, education, rest, and rehabilitation, rather than secondary to lowered serum lipid levels We believe that, when the mechanisms of these dietary effects are better understood, more practical methods for influencing serum lipid levels will become obvious At that time it may be possible to make critical tests of the hypothesis that atherosclerosis is fundamentally a disorder of lipid metabolism

Summary

The hypothesis that dietary fats affect atherogenesis, however plausible and appealing, remains unproved Serum lipids can be altered by dietary means, and experimental data lead to the presumptive conclusion that unsaturated fats in the diet cause depressions in levels of cholesterol and phospholipids Serum triglycerides, on the other hand, can be made to rise on low-fat diets and to fall when fat intakes are high Thus, serum lipids are affected by both quantity and quality of ingested fat Radical changes in dietary habits are not recommended to the general public at this time However, patients with existent or threatening arteriosclerosis may be justifiably advised to eat higher proportions of unsaturated fats

DIET AND THE EPIDEMIOLOGY OF CORONARY HEART DISEASE

Ancel Keys, Ph.D., Minneapolis

Researches ranging from laboratory experiments to epidemiology on a world-wide basis have led to the hypothesis that the fat content of the habitual diets of populations has an important effect on the frequency of coronary heart disease in those populations. The general nature and some of the evidence for this hypothesis have been summarized several times in recent years,[1] but progress in this field manages to outdate each new resume by the time it reaches print. Not that the previously cited facts or the hypothesis itself have been found to be erroneous, on the contrary, each new research adds detail, reduces areas of uncertainty and, so far, provides further reason to believe that along the line of this hypothesis we may hope to find effective measures to reduce the incidence of coronary heart disease.

As it now stands, the hypothesis may be stated simply as follows. Though many factors of nature and nurture may be involved in the multiple etiology of coronary heart disease, the development of the majority of cases in populations that suffer most from it, for example, the United States, is dominated by the long-time effects of a rich fatty diet and innumerable fat-loading meals. Among the results of the fatty diet are hypercholesteremia, which promotes atherosclerosis, and changes in the coagulability and other characteristics of the blood that favor thrombosis and inhibit fibrinolysis. All food fats are not identical in promoting hypercholesteremia, but those most favored and abundant in almost all fatty diets are more powerful in this direction than are those food oils that have an opposing effect. Further, the differences between the fats in respect to their effect on the serum cholesterol level are not paralleled by differences in their influence on blood coagulation.

New evidence supporting this hypothesis includes findings in regard to (1) the predictive value of serum cholesterol measurements, (2) errors in the argument that the Eskimo and the Navajo discredit the hypothesis, (3) the lack of effect of dietary cholesterol in man, (4) failure of alterations in dietary protein in man to affect the blood response to dietary fat, (5) the relative independence of population differences in serum cholesterol level from differences in physical activity and the frequency of obesity, (6) differences between Japanese living on different diets, (7) the frequency of coronary heart disease in rural eastern Finland, (8) the infrequency of thromboembolic phenomena in general in populations on diets low in fats, and (9) clarification of the cholesterol elevating and depressing effects of different dietary fats. The present discussion can only touch on each of these items briefly.

Predictions from Serum Cholesterol

It is well established that patients with coronary heart disease tend to have higher serum cholesterol concentrations than their clinically healthy counterparts. It is also known that patients with disorders generally involving elevated serum cholesterol levels—diabetes, myxedema, nephrosis, familial hypercholesteremia—are unduly prone to coronary heart disease. But the question has been asked as to whether the serum cholesterol concentration in the apparently 'normal' person has any predictive value about the development of coronary heart disease.

This question has now been answered in the affirmative from the cooperative study in which blood measurements were made on clinically healthy men who were then observed for about two years, during which time evidence of coronary heart disease appeared in some of the men.[2] It was found that 41 of 57 men in whom coronary heart disease developed had serum cholesterol levels, before the disease was clinically apparent, above the median for the entire group originally examined. Compared with this test, the widely publicized ultracentrifugal analysis of the Donner Laboratory in California did less well, although the difference between the two tests is not statistically significant. Basic data are given in table 1.

It should be observed that almost all of these "new coronary" cases were in men with serum cholesterol values, before the event, that would be considered unusually high in populations in which severe atherosclerosis and coronary heart disease are relatively rare, such as in Japan and among the Bantu. It seems that most middle-aged American men have hypercholesteremia in terms of the world distribution of serum cholesterol values. Autopsy studies indicate, further, that most middle-aged American men have severe coronary atherosclerosis. These facts are compatible with the theory that atherosclerosis is in considerable measure a reflection of the habitual serum cholesterol concentration.

The cooperative study previously mentioned, in fact, was not a test to see whether cholesterol measurements will detect or predict the presence of atherosclerosis. Even as a test to discover whether coronary heart disease can be predicted, it only examined the question of prediction of the appearance of the disease in the relatively near future—in a year or two. The "yield" of "new events" was small, not because only a few of the men examined will develop the disease, but because only a few will do so in a year or two. Eventually, several thousand, instead of less than 100, of these men will suffer from coronary heart disease if they behave in general like the white male population in the United States.

An occasional serum cholesterol measurement does not yield a reliable prediction of the danger of coronary heart disease for the individual, nor should it or any other measurement be expected to do so. At best, any blood measurement could only indicate the atherogenic potential of the blood at the time of blood sampling. In American men, at least, coronary atherosclerosis is often well marked before they are 30 years old, so that the clinical appearance of the disease in

---

Director of the Laboratory of Physiological Hygiene, School of Public Health, University of Minnesota.

men in the 50s represents the cumulative effects of many years Further, even if we grant that serum cholesterol concentration is a major factor in atherogenesis, it must be observed that atherosclerosis itself is not the only factor in the development of coronary heart disease, though it may be a necessary basis in that development in most cases

On the other hand, serum cholesterol concentration appears to have high predictive value for populations This much can be said no population characterized by low serum cholesterol values has yet been found to have a high incidence of atherosclerosis or coronary heart disease

The Case of the Eskimo

Though Eskimos are an exceedingly small group of atypical people, their bizarre manner of life excites the imagination, including that of medical writers, who have been wont to endow them with a remarkable freedom from some of the ills that beset the rest of us Since the popular picture of the Eskimo sees him happily gorging on blubber, it is a short step to conclude that he eats a very high fat diet but suffers no coronary heart disease

TABLE 1 —*Blood Serum of 40 to 59-Year Old Men Who Developed Coronary Heart Disease Compared with Median (50th Centile) Values for Clinically Healthy* Population and with 80th Centile for Cholesterol in 303 Japanese Men, 40 to 59*

Measure		Total Patients	No Above 50th Centile	No Above Japanese 80th Centile
Ultracentrifuge	Sf 12 20	65	32	
	Sf 20-100	65	42	
Total Cholesterol		57	41	54

* See footnote 2 p 712 table 14

The fact is that nothing is really known about the incidence of atherosclerosis and coronary heart disease among Eskimos According to Ehrstrom,[3] arteriosclerosis is common among them, reaching an incidence of 29% in North Greenland, but the evidence is dubious, particularly in regard to atherosclerotic heart disease In any case we could not expect a high incidence of coronary disease among primitive Eskimos because few of them attain an age when they would be likely victims of the disease The majority of Eskimos no longer eat a high-fat diet,[4] and of those who adhere to the old way of life probably not more than a total of 100 or so men are beyond the age of 50, though estimates are difficult in a widely dispersed population who do not know their own ages and are notorious for appearing far older than their years

The diets of primitive Eskimos have been studied repeatedly, and they were, indeed, high in fat, but scarcely more so than the average U S Army diet However, the resemblance between the diets of Eskimos and American soldiers is confined to this one item, the primitive Eskimo diet was extraordinarily high in proteins, some 45% of calories versus around 13 to 14% in American diets, and the kind of fat differed greatly, being mostly derived from fish and marine animals and including practically none of the ordinary meat and dairy fats that bulk so large in the American diet

The net result is that on no grounds is it possible to suggest that the case of the Eskimo contributes anything, and certainly no exception, to the diet fat-coronary heart disease hypothesis

The Case of the Navajo

The idea that the Navajo is instructive in regard to the diet and coronary heart disease was put forth in a paper in which the only data are some serum lipid values for Navajo patients at the Fort Defiance Indian Medical Center[5] But the real point of the paper is the statement by the authors that 'Navajos usually eat a typically American diet," from which they go on to emphasize that 'coronary heart disease among them is rare" It is inferred that Navajos eat the same diet, including the fats, as the rest of us in the United States but that they have low serum cholesterol values and almost never have coronary heart disease

The dietary information on which these statements were based consists of the replies of 100 Navajo patients to questions as to how often they ate certain foods These data, not given in the paper just noted, were made available earlier by Dr Gilbert[6] and are reproduced here as table 2 Very similar replies were obtained by Darby and co-workers[7] from a larger sample of Navajos questioned at Ganado and Piñon, settlements more central in the reservation than Fort Defiance

How many 'typical white Americans eat meat, in any form or amount, less than once a day? Gilbert's data indicate that 55% of the Navajo men at Fort Defiance are in this category, at Ganado the figure is reported as 41% and at Piñon it is 56%[7] In regard to milk, the question of form and amount is particularly important The percentages of Navajos who have some milk daily are reported as 68%, 81%, and 61% for Fort Defiance, Ganado, and Piñon, respectively, but our dietary team found that this "milk" is almost exclusively simply evaporated milk used in coffee

The Navajo Reservation Extension Report for 1953 lists the livestock inventory as 17,000 beef cattle, 387,000 sheep, and 68,000 goats but that there were no dairy cows, poultry, or swine 'Meat' to the Navajo generally means mutton and goat meat, they eat extremely little beef and substantially no pork or poultry The total meat consumption per capita amounts to 2 7 oz daily for the Navajo, according to the Extension Report data, for the U S as a whole the figure is 6 4 oz for beef and pork alone, and poultry contributes another 1 3 oz Apparently, the meat fat intake of the Navajo is something like one-fourth to one-third that of the U S average, and the discrepancy in regard to butterfat is much greater

TABLE 2 —*Eating Habits as Stated by 100 Navajos at Fort Defiance**

Food Item	% of Navajos Eating Items Less than		
	Twice Daily	Daily	Twice Weekly
Meat	60	55	34
Lard	61	34	16
Eggs	99	83	59
Butter	98	89	79
Milk†	91	68	59

* Data from Gilbert[6]
† Almost solely condensed milk in coffee

We found it very difficult to get quantitative estimates of the nutrients in Navajo diets We were able to obtain records of lard purchases as well as of other staples, including flour, sugar, and potatoes, in the Fort Defiance community For nine families, who produced no food of their own and were thought to be typical by the local post agents, complete purchase records of all foods could be obtained for periods of several months The calories supplied by all fats, including invisible fats ranged from 18 to 34% of the total calories in the diet, and most of the fat was in the form of lard Table 3 gives the data for a family that seemed to be in the center of the diet distribution The average is 25 5% of calories from fats, with only 5 2% being from meats, eggs and dairy products, as compared with the United States national average figures of something over 40 and 25% respectively This is a diet much like we found in Sardinia, except that lard takes the place of olive oil

From what is known of the Navajos and their diet we should expect a low incidence of coronary heart disease Certainly it would be predicted that myocardial infarctions would not often be seen in this small, widely dispersed population in which children are more numerous than adults This is a relatively primitive society, afflicted by the conditions that lead to a low average age According to census returns, only 14% of Navajos are 45 years old or older, the corresponding figure for United States whites is 30%

Table 3 —*Sources of Calories in Diet of Typical Navajo Family from May until August*

Item	% of Calories	
	Total	As Fat
Lard	18 0	18 0
Meat and eggs	5 9	4 1
Flour bread cornmeal	44 1	1 2
Sugar jam candy pop	15 0	0 7
Potatoes	12 7	0 2
Evaporated milk and ice cream*	2 2	1 1
Beans vegetables fruits	2 1	0 2
Total	100 0	25 5

* Three pints of ice cream bought in 9 weeks

But coronary heart disease is not vanishingly rare among the Navajos In the year 1955-1956, among a total of only 115 men patients admitted to the medical division of the Indian Medical Center Hospital, there were 8 diagnoses of arteriosclerotic heart disease and 2 myocardial infarcts From what we know of the diet, this is at least as many as we should expect on the basis of the diet fat–coronary hypothesis No one knows the actual age-specific incidence or mortality, but it is clear that there is no basis for claiming that the Navajo is an "exception to the rule observed in other populations

Lack of Effect of Dietary Cholesterol in Man

The fact that various animal species differ greatly in cholesterol metabolism, at least in quantitative terms, long caused confusion between the effects in man of fats and of cholesterol in the diet In contrast to the extreme sensitivity of the rabbit and the chick to cholesterol in the diet, man is remarkably resistant In the range of zero to as much as 2 Gm of ingested cholesterol per day, human blood serum shows practically no relationship with the intake, either in controlled experiments or in comparisons between persons and population groups whose diets differ greatly in cholesterol content but are otherwise comparable[8]

Even tremendous dosages of cholesterol added to the daily diet of man—up to 30 Gm per day—have only a trivial effect unless the dietary cholesterol is accompanied by additional fats Since natural human diets rarely surpass 1 Gm of cholesterol per day, the convincing evidence that the human serum concentration is so resistant to exogenous cholesterol means that for all practical purposes the dietary cholesterol variable may be disregarded and attention concentrated on other characteristics of the diet

Unimportance of Dietary Protein

Human populations characterized by low serum cholesterol levels and relative freedom from atherosclerosis sometimes subsist on diets that are low in proteins as well as in fats The question then arises as to whether the diet protein contributes to the findings in the blood and the arteries In some animals, the combination of high cholesterol feeding and diets low in proteins, particularly in sulfur-containing amino acids, produces hypercholesteremia and atherosclerosis[9] Such an effect of protein is obviously in the opposite direction to an effect that would explain the rarity of coronary heart disease in human populations, such as the Bantu, whose diets are low in fats and proteins, but this fact has been ignored by some enthusiasts who hopefully seek to ascribe hypercholesteremia in man to deficiency rather than to excess of some nutrients in the diet

Large daily supplements of methionine had no effect on the hypercholesteremia of American men who continued on their usual diets without other alterations[10] In completely controlled experiments on groups of men we found that the isocaloric exchange of carbohydrate and animal protein (casein), so that the diets covered the range from 11 to 20% of calories from proteins, was without effect on the serum cholesterol level and that changes in the protein intake did not modify the usual response to changes in the fat content of the diet[11] It is well known, of course, that the rice diet, which is low in both proteins and fats, is an effective means for lowering the serum cholesterol level in man That the low fat, and not the low protein characteristic of the rice diet is primarily responsible for the serum cholesterol effect, is readily shown by the fact that the addition of butterfat or beef fat to diets of this type will prevent the fall in serum cholesterol level that occurs otherwise In our laboratory an early method of assaying the effects of fats on the serum cholesterol level was to use essentially a rice diet for some weeks and then to substitute, isocalorically, fat for part of the carbohydrate in the rice diet

Finally, it should be observed that, though a few populations have diets low in both proteins and fats, most of the populations of concern in these comparative population studies have diets that vary little in protein content though there is great variation in dietary fat The percentages of calories provided by proteins in the diets of the populations of Japan and Italy with a low incidence of coronary disease are almost identical with the corresponding values for populations of the United States and Finland with a high incidence of coronary disease

Physical Activity Versus the Diet

In many populations in which the serum cholesterol level is low and coronary heart disease is relatively rare, heavy manual labor is more common than in the United States and some other areas where the incidence of coronary heart disease is very high This fact, coupled with the reports of the Registrar General of England and Wales, going back to 1931, about differences between social classes in mortality rate ascribed to arteriosclerotic heart disease, gave rise to the theory that physical inactivity promotes the disease

J N Morris and his colleagues have emphasized the effect of lack of exercise and have produced data on postal employees and London busmen in support[12] The cited differences between "active" and 'inactive" postal employees are trivial, but among the busmen it was found that the "sedentary drivers" suffered about twice as many occlusions, at the same age, as did the active" conductors The interpretation of this finding, however, has recently become more questionable than at first sight because of the discovery that the two groups of employees were different in at least one major respect before they embarked on their careers of different levels of activity[13] As figure 1 shows, at the outset the drivers were much more often fat, as indicated by trouser-waist size, than the conductors As they stayed on in their jobs, both groups tended to get fatter and fatter, but the basic difference between the groups persisted

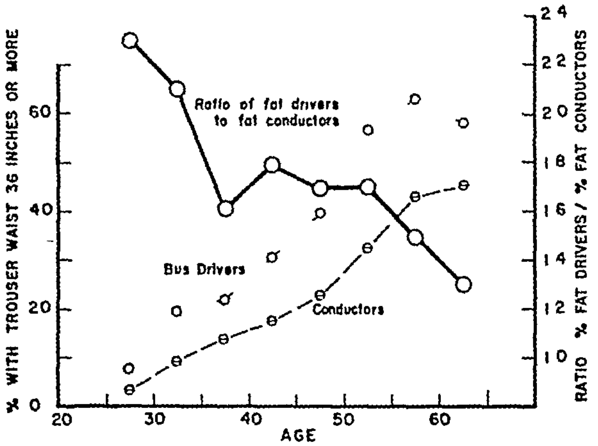

Fig 1 —Frequency of trouser-waist size 36 in or more issued to 2,270 London bus drivers and conductors Data from Morris, Heady, and Raffle[13]

In any case, differences in physical activity are frequently accompanied by differences in the proportion of fat in the diet As activity increases, the demand for calories follows suit and the tendency is for the extra calories to be obtained from the staple carbohydrate foods, without a proportionate increase in meats, dairy products, and other high-fat foods[14] This is illustrated in table 4 by comparisons of two types of employees in the same place and by the comparison between rural and urban dwellers, who generally differ considerably in their exercise habits Greater differences than these between heavy and light workers are indicated from semiquantitative data obtained in Sweden and South Africa[14]

Table 4 —*Comparison Between Sedentary (Urban) Versus Manual (Rural) Workers in Regard to Percentage of Calories Provided by Fats in Diet**

Group	% Calories from Fats	
	Sedentary (Urban)	Manual (Rural)
Drug factory employees U S	40 4	37 0
Mine company employees Scotland	35 3	33 5
U S urban vs rural	42 0	37 0
Japan urban vs rural	9 7	6 4

* Data from Keys and others[14]

The rather regular progression of coronary heart disease mortality with social class reported from England, and loosely attributed to physical activity, is not confirmed by recent studies in the United States[15] and in Norway The very careful cooperative study of myocardial infarction in Oslo[16] not only confirms previous reports of the large change during the war years when the local diet was low in fats, but clearly fails to show any large differences between the incidence in men in different occupations Rationing began in Norway in 1939, and food shortages, especially in fat, were seriously felt by the latter part of 1940 The first change in mortality ascribed to heart disease was noted for the year 1941, and thereafter the mortality rate from this cause fell steadily until 1945, when fat imports were resumed Cardiac mortality rose slightly in 1946 and continued to rise thereafter, but the prewar rate was not regained until after 1949 Relevant data are summarized in table 5

Certainly physical activity does not explain the large differences in serum cholesterol concentration observed between populations eating different amounts of fats[15] These differences persist when the men in the several populations are matched in regard to physical activity as well as in age Table 6 summarizes the findings in one occupation category city policemen and firemen in five regions differing in the percentage of calories provided by fats in the diet It may be noted, too, that the frequency of obesity in these men was unrelated to the serum cholesterol level, the fattest men in table 6 were those in Minneapolis, but

Table 5 —*Percentage Distribution of Men Under 70 with Myocardial Infarction According to Occupation in Oslo and Aker, Norway, in 1935-1949, Together with Expected Approximations from Census Returns for Distribution of Ages and Occupations**

Occupation	% Observed	% Expected
Employers	13 7	14 8
Executives	5 2	3 4

* Data from Life Insurance Companies Institute 1956

when the fattest of these men are omitted (all those with relative body weights of 112 or more) the serum cholesterol average is unchanged Similar regularity in the relationship between dietary fat and serum cholesterol characterizes matched samples of sedentary men and of men doing very heavy manual work

The Case of the Japanese

Of all large countries that provide detailed vital statistics, Japan reports the lowest mortality from coronary heart disease, the 1953-1954 death rate for men aged 50-54 being less than a tenth that for white American men, while the rate for women of the same age is less than a fourth that for white American women That these differences are something like the true figures is indicated by a large study on the frequency of severe coronary atherosclerosis found in routine autopsies in southern Japan [17] and by the good agreement between cardiovascular mortality in the vital statistics and the morbidity found in a nationwide health survey in Japan [18]

TABLE 6 —*Serum Total Cholesterol Means (and Standard Errors) in Firemen and Policemen Aged 40 to 51 in Various Cities, Together with Mean Relative Body Weight and Approximate Percentage of Calories Supplied by Fats in Diet*

* Omitting 41 men with relative body weight of 112 and over

In 1956, a team from the United States, including Dr Paul Dudley White and Dr B Bronte-Stewart in addition to myself, studied the situation in southern Japan It was abundantly clear that angina pectoris and myocardial infarction are indeed uncommon there, both in the large hospitals and in the small private clinics This is not dependent on a relative scarcity of older people in Japan or a very high death rate from other causes As a matter of fact, the total death rate (all causes combined) for middle-aged men in Japan is less than that for the United States, in spite of the fact that tuberculosis is still a major problem in Japan, with a death rate four or five times that in the United States

It was important, therefore, to study diets and serum cholesterol levels among Japanese This was undertaken in cooperative researches in Fukuoka Prefecture, Kyushu, in Hawaii, and in Los Angeles [19] Five groups of Japanese men were studied on the Island of Kyushu Dietary and serum cholesterol data on those aged 40-49, inclusive, are summarized in figure 2 The relationship between these variables for the men in Japan conforms to what we have found in non-Japanese populations elsewhere For comparison we studied Japanese in Los Angeles, where, as figure 2 shows, the local "Nisei" have adopted the usual American diet, and in Hawaii, where the Japanese have moved far toward the typical American diet but are still intermediate between Japan and the United States in this regard

As in our other population comparisons, the differences between the various Japanese groups in serum total cholesterol level are entirely accounted for by differences in the beta-lipoprotein cholesterol concentration, the average alpha-lipoprotein cholesterol concentration remains narrowly within the range of about 36 to 44 mg per 100 ml of serum and shows no trend to vary with the diet Also, as in our other population comparisons, the cholesterol differences are not dependent on differences in relative obesity, though the frequency of obesity rises in the order from Japan to Hawaii to Los Angeles For example, by omitting the thinnest men in Shime and the fattest men in Los Angeles, we were able to match in relative fatness 25 men each in Shime, Hawaii, and Los Angeles, all aged 40-49 and all engaged in light or sedentary work The average serum beta-lipoprotein cholesterol concentrations for these groups were 124 8, 178 2, and 206 0 mg per 100 ml, respectively

The frequency of atherosclerosis and coronary heart disease among Japanese in Hawaii and in California corresponds, at least roughly, with the cholesterol and dietary findings The frequency of severe atherosclerosis among Japanese in Hawaii has been studied recently,[20] and we have checked the data to assure comparability with the autopsy data in Minnesota and Kyushu The result is that the frequency of grades 3 and 4 (on a scale of 0 to 4) atherosclerosis in routine autopsies, all causes of death, in middle aged Japanese men in Hawaii is about half that seen among local Caucasians there (or among men in Minnesota) and some five times greater than among men in Kyushu Comparable data are not available for Japanese in California, but the frequency of coronary heart disease there in the Japanese Hospital and in the practices of Los Angeles physicians is certainly much higher than among Japanese in Hawaii Further, according to the vital statistics, coronary heart disease is the leading cause of death among Japanese in California, just as it is among the native white population

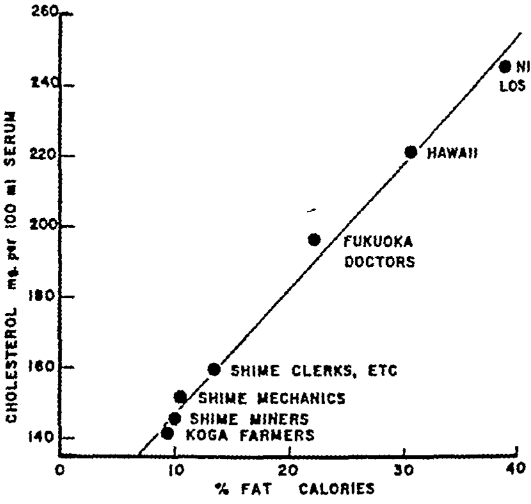

Fig 2 —Mean serum total cholesterol level and the average percentage of calories provided by total fats in the diets of 284 clinically healthy Japanese men aged 40-49 years in seven groups

In Japan, as in Hawaii and Los Angeles, most Japanese men smoke heavily, indulge regularly in alcohol, dodge traffic, are slaves to the alarm clock, the radio, and telephones, complain about bureaucracy and taxes, worry about inflation, and are avid sports fans Business operations are intricate, giant banks and industrial concerns dominate the economic scene, competition is keen, labor is restless, and farmers demand (and get) subsidies Fathers despair of the younger generation and cannot understand how their wives' new clothes can cost so much But, though alike in so many ways, Japanese in Japan, in Hawaii, and in California differ in their diets, in their serum cholesterol concentrations, and in their proclivity to develop coronary heart disease

Studies in Finland

Finland *is less industrialized* than Japan, a large proportion of the population is strictly rural and lives widely scattered in the quiet countryside There is little housing congestion, motor traffic is light, hard physical work is the rule rather than the exception, and probably no other country can boast so high an average level of physical fitness According to some ideas, Finland should be peculiarly free from coronary heart disease, but according to vital statistics it competes with the United States in the great frequency of the disease

For these reasons, and because the level of Finnish medicine and medical services and records is very high, systematic research on coronary heart disease and the mode of life in Finland was begun in May, 1956, with a collaborative group including professors Paul Soisalo and Paavo Roine and Dr Martti Karvonen This work is still in progress, but several facts are already clear

First, the frequency of coronary disease is indeed very high[21] Table 7 summarizes the experience in 1954 of the two big general hospitals of Helsinki The accuracy of diagnosis and comparability to diagnosis in the United States was checked in the Kivela Hospital by Dr Paul Dudley White Among all medical inpatients, excluding those with infectious, parasitic, and mental diseases, 13 8% of the patients had coronary heart disease (International List No 420 and 422) and 18 9% of the deaths were caused by it

Perhaps even more striking is the experience of the Joensuu Central Hospital, in a town of 20,000 but caring mainly for the farming and woodcutting population of the area It was found that about 10% of the patients in the 92 beds of the medical division have suffered myocardial infarction with typical electrocardiographic findings In the years 1954 and 1955, among 172 patients with myocardial infarction, 54 (including 9 women) were under the age of 50 years

The second point of interest from the work in Finland is the frequency of very high levels of serum cholesterol observed in samples of the population in rural east and west Finland as well as in Helsinki In Helsinki the average serum total cholesterol concentration in two groups of men aged 40-49 (members of the Helsinki fire department and members of the Helsinki Rotary club), studied in collaboration with Dr Martti Karvonen and Dr Flaminio Fidanza, was over 260 mg per 100 ml, higher than in any other population samples studied in these world-wide researches

The third point from the Finnish research is the fact, emerging from the careful dietary surveys conducted by Professor Paavo Roine and his colleagues, that the average amount of fat in the diet is high and the per capita consumption of butterfat is one of the highest in the world

The research in Finland, then, though far from completed, shows that there is at least one predominantly rural population in the world who live at a high rate of energy expenditures but who have a very high incidence of coronary heart disease Further, from what is known of the diet of this population, the coronary picture is consonant with the hypothesis about the importance of dietary fat

Thromboembolism in Relation to Low-Fat Diets

Insufficient attention has been paid to the frequency of thromboembolic phenomena in general in relation to the character of the diet It seems to be well established that postsurgery, postpartum, and post-trauma thromboembolic complications are very rare in southeast Asia, where the diets are low in fats, as compared with the incidence in northern Europe and the United States[22] In Africa and Asia, in my discussions about this with surgeons and inspection of hospital records, the pattern was consistent wherever the diet was low in fats, thromboembolic phenomena of all kinds were rare

Table 7 —*Experience of Medical Departments of Two Hospitals in Helsinki in 1954*[*]

	Hospital		
Category	Maria	Kivela	Total
Total inpatients	6 184	8,754	14 938
Total deaths	336	597	923
Coronary inpatients†	776	1 281	2 057
Coronary deaths	55	119	174

† International Lists no 420 422.

Strong evidence as to the reality of a relationship between dietary fat and the tendency toward thrombosis was obtained from an analysis of the experience in the hospitals of Oslo during and after World War II[23] During the period of subsistence on low-fat diets the incidence of thromboembolic complications after major surgery in Norway fell to less than a third of the prewar incidence, and it rose to reach or surpass the prewar level as the dietary fat was restored in the postwar years The change in this respect was even more striking that the well-known change in the mortality rate from coronary heart disease during that period in Norway and suggests, indeed, that some of the wartime decline in coronary deaths may have reflected a general decreased tendency toward all kinds of thrombosis In other words, it is unnecessary to postulate a major change in atherosclerosis to account for all of the alteration in coronary mortality

Part of the explanation for such differences in the frequency of thrombosis may be at hand in the fact, now established, that a fatty meal often induces a state of relative hypercoagulability of the blood for some hours[24] It is possible also that, as recently reported, inhibition of fibrinolysis after a fatty meal may be involved[25] It is clear that the thrombosis side of the coronary heart disease problem has been neglected in the recent concentration on atherosclerosis but that it, too, may well involve dietary fat

Serum Cholesterol Response to Different Dietary Fats

The precise relationship between the serum cholesterol concentration and the fats in the diet of man has been somewhat confused by the finding in laboratory experiments that not all fats have the same effect on the blood serum cholesterol and cholesterol-containing lipoproteins This question has been less prominent in epidemiologic studies because, in most populations, the fats added to the diet as the diet fat is increased run to a common pattern of meat and dairy fats and these are the fats commonly removed when the diet is changed to a low fat level In other words, in most situations the kind and the amount of fat change is parallel

In any case it now seems to be possible to predict with fair accuracy the serum cholesterol response to a change in the amount or character of the fat in the diet This has been found with the data from six years of dietary experiments on groups of men under completely controlled conditions[26] The fats tested include coconut oil, olive oil, lard, corn oil, cottonseed oil, sunflower seed oil, butterfat, safflower seed oil, and sardine oil as well as the mixed fats of the usual American diet The amounts of the fats tested range from about 8 to slightly over 40% of the total calories of the diet

If the dietary fats are expressed in terms of the percentages of total calories in the forms of saturated, monoethenoid, and polyethenoid fatty acids (as the glycerides), statistical analysis of the average serum cholesterol differences of the same men receiving different fats shows that monoethenoid fatty acid (oleic acid) has relatively little effect, but saturated fatty acids raise the serum cholesterol level whereas polyethenoid fatty acids (chiefly linoleic acid) lower it Further, 69 sets of dietary comparisons clearly show that, per gram of fat, the saturated fatty acids have twice as much effect as the polyethenoid fatty acids, including linoleic acid It was found also that the extremely unsaturated fish oils have no greater effect than does cottonseed oil Apparently additional points of unsaturation beyond two double bonds have no effect

In practical terms, these newly found relationships show that 1 Gm of butterfat has about three times as much effect as 1 Gm of corn oil or sunflower seed oil The removal of 1 Gm of butterfat from the diet has about the same serum cholesterol lowering effect as the addition of 3 Gm of one of the high linoleic acid oils

These systematic studies explain many confusing points in the literature on dietary experiments, they explain the consistency of the relationship between total dietary fat and serum cholesterol in epidemiologic studies, and they provide sound guidance for dietary alterations Among other things, it is now evident that the effort to control the serum cholesterol level merely by adding unsaturated or linoleic acid fats to the diet is doomed to failure because the amount required to achieve much consequence would involve an impossibly large addition of calories On the other hand, it is clear that it is unnecessary to prescribe a diet extremely low in total fats to lower the serum cholesterol, exclusion of the saturated fats (in butterfat and meat fats) has the greatest effect, and this effect may be enhanced by substitution of such oils as corn oil and cottonseed oil

As a practical matter it would seem undesirable to use a high-fat diet of any fat composition because of the high calorie density it provides, with the resulting danger of producing obesity, and because of the possible undesirable effects on blood coagulability and fibrinolytic power

Conclusions

The hypothesis that the diet, through its fat content, plays an important role in the development of coronary heart disease, is sustained by a wide variety of new evidence from both laboratory experiments and epidemiologic studies It appears probable that the dietary fats exert their effects not only through affecting the serum cholesterol level and thus influencing atherogenesis but also through effects on the tendency to develop thrombosis Although the more unsaturated fats may not promote hypercholesteremia, the more powerful effect of the saturated fats is such that blood cholesterol levels cannot be satisfactorily controlled unless the saturated fat intake is reduced With a judicious choice of fats in the diet, serum cholesterol level can be controlled without imposing extremely low-fat diets But the use of diets very high in any kind of fats seems undesirable because of the high calorie content of such diets and because of the possibility of undesirable effects on blood coagulation and fibrinolysis

The facts cited in this paper are, or will be, separately published in detail, with appropriate acknowledgments to the many persons and organizations who have been involved in the work But here special mention should be made of those individuals whose collaboration and assistance was important in the researches not yet reported in full Research on Japanese men—Drs Noboru Kimura and Akira Kusukawa of Kyushu University Medical School, Dr Masakazu Yoshitomi of the Shime Hospital, Dr B Bronte-Stewart, now at Oxford University Medical School Dr Nils P Larsen of Honolulu, Mrs Margaret H Keys of St Paul, Mrs Shizuko H Miyamoto, now of Santa Ana, Calif, and Drs John L Denny, Benjamin Kondo, and Tom Watanabe, all of Los Angeles Research in Finland—professors Paul Soisalo and Paavo Roine, Drs Martti Karvonen, Flaminio Fidanza, and Pir Ahrenberg Experiments at Hastings—Drs Joseph T Anderson and Francisco Grande Data on Navajos—Mrs Nedra Foster, Mrs Margaret H Keys, Mr Robert W Young Assistant to the General Superintendent of the Bureau of Indian Affairs Navajo Agency, and Dr David L Duncan, Assistant Area Medical Officer, Window Rock Office, Department of Health, Education and Welfare Clinical Evaluations—Dr Paul Dudley White

The data reported here were obtained in part with the support of funds provided by the American Heart Association, the National Dairy Council, Chicago, the Finnish Heart Association, Helsinki, the Minnesota Heart Association, the American Dairy Association Chicago, the Nutrition Foundation, New York the Schweppe Foundation, Chicago, the Winton Companies Fund, and Mr David Winton, Minneapolis

Children's Skin Tumors—Nevi are the most common tumors of childhood Pigmented nevi are classified into blue nevi, intraepidermal nevi, junction nevi, intradermal nevi (or common mole) and combination types Cutaneous malignant disease in children is rare Malignant melanoma is rare before puberty Wholesale removal of benign pigmented nevi in children should be condemned However, junction nevi located on the palms, soles, genitalia or waistline—that is, in areas subject to frequent trauma—should be excised Hemangiomas in infants are the most common tumors for which advice is sought Not all hemangiomas regress spontaneously, and on occasion the persistence or progression of such a lesion may bring about life-long unsightly deformities Therapy for this type of tumor is simple when given early in life Since a few topical applications of solid carbon dioxide or liquid nitrogen will easily and effectively eliminate tumors of this type, it seems foolhardy to permit such a lesion to increase tremendously in size Strawberry marks that undergo involution, spontaneously or as a result of trauma, may heal with conspicuous scarring or change into a mixed fibrovascular structure It is generally agreed among dermatologists that irradiation, particularly with radium, is the treatment of choice for cavernous hemangiomata (deep type) if given at an early age The best and quickest results are obtained if treatment is begun before the third month of life when endothelial cells of the vascular channels are still immature Injection of sclerosing solutions is the next most widely used method of treatment Hemangiomas involving the ears, nose, lips or eyelids should be treated at once, preferably within a month of the time they appear —B A Newman, M D , Cutaneous Tumors of Children, *California Medicine*, January, 1957

NUTRITIONAL STUDIES RELATING TO SERUM LIPIDS AND ATHEROSCLEROSIS

THERAPEUTIC IMPLICATIONS

Fredrick J Stare, M D, Theodore B Van Itallie, M D, Mary B McCann, M P H
and
Oscar W Portman, M D, Boston

Most of us in research feel somewhat hesitant about "answers' to the many questions on therapy that arise in connection with any rapidly changing area of investigation Yet, perhaps we do have a responsibility to attempt to provide today's answers for today's questions This paper is made up largely of questions and answers These are not fictitious questions, almost all of them have come to us from physicians The following statements concerning experimentally induced atherosclerosis will provide a background

Atherosclerosis is induced experimentally in several species of animals, including primates, usually only when the level of total cholesterol in the serum is increased There are both intensity and time factors, the greater the elevation of cholesterol, the less time needed to produce lesions of atherosclerosis In our experience, the earliest lesions are found under the endothelium of the aortic and mitral valves, the portion of the septum between these valves, the aorta, and then the coronary vessels True intimal plaque formation is obtained later

Coronary thrombosis with myocardial infarction has rarely been seen in connection with experimentally induced atherosclerosis, so rarely that it would be difficult to say that it had been produced experimentally Myocardial infarction has occurred in experimental animals only in association with extensive atherosclerosis and hypercholesteremia At this meeting a report has been made by Dr W Stanley Hartroft and his colleagues of the production of coronary thrombosis in rats This is of considerable interest, but until the original data is available for study and the observations have been confirmed it is not possible for us to comment further

The amount and the type of fat in the diet affect the development of experimental hypercholesteremia in rats and monkeys Studies with experimental animals suggest that the serum cholesterol level is more responsive to the type than to the quantity of dietary fat In general, diets containing fats that are rich in polyunsaturated fatty acids, such as corn and cottonseed oils, are associated with lower levels of cholesterol in the serum than are diets in which the monounsaturated and saturated fatty acids predominate There are several indications that total unsaturation of fat by itself, as measured by iodine value, or even total linoleate by itself, is not an accurate gauge of the effect of the fat on the serum lipids

Use of heparin and other anticoagulants under careful supervision represents a forward step in the therapy of coronary thrombosis Although the heparin like anticoagulants accelerate the disappearance of various lipid fractions from the blood, not much is known about their effect on the development of experimental atherosclerosis in animals or of atherosclerosis in man In our opinion, the therapeutic use of anticoagulants in man today is not in the realm of nutritional studies and will not be further considered in this paper

What about sitosterols? So far, 11 investigators have published clinical studies in which sitosterol has caused significant reduction of the serum cholesterol level in most but not all hypercholesteremic patients Two studies have reported sitosterols to be essentially ineffective

The eventual usefulness of sitosterol in controlling hypercholesteremia cannot be predicted with confidence on the basis of the present evidence It would seem that reductions in the serum cholesterol level can be obtained with the administration of adequate amounts of plant sterol before each meal The physical characteristics of the preparation may make acceptance by patients somewhat difficult owing to the chalky nature of the material These compounds may act not merely by blocking the absorption of dietary cholesterol, but they may also inhibit the reabsorption of biliary and enteric cholesterol

What about lipotropic substances, such as choline, methionine, and inositol? Under certain experimental and clinical conditions these substances may be limiting factors in fat transport and metabolism Their role in the regulation of serum lipid levels and in the metabolism of fat in arterial tissue is less clear We know of no evidence that such lipotropic substances have a useful role to play in the prevention or treatment of atherosclerosis in man

Question As a doctor interested in preventative medicine, should I urge dietary change for the public and for all my patients as a possible means of reducing the incidence of atherosclerosis?

Answer Not at this time To the public in general, current research on atherosclerosis provides hope that important advances in this field may be at hand However, no developments have occurred to justify a marked change in our current concepts of a well-balanced, moderate diet suited to the living habits of the individual Researches on atherosclerosis involve a variety of epidemiologic and statistical studies and observations on persons under rigid dietary control

---

From the Department of Nutrition Harvard School of Public Health

In addition a variety of animal studies have been done and others are in progress Although all of this work is of interest and of potential value, it has not, in our opinion, conclusively established any single dietary factor as being the cause of atherosclerosis much less the cause of coronary thrombosis

Question Are fats just empty calories? Is it necessary to have them in our diets?

Answer Some fat is important in the diet It may well be that some of us are eating too much fat or too much of certain types of fat, but there may also be many persons who are leading active lives who do not get enough fat Fat is a concentrated source of energy and is needed to provide adequate calories without undue bulk for people who have considerable physical activity Calories, whether empty or not, are still necessary!

Fat is important to us in preventing hunger between meals The satiety value of fat is frequently a factor in reducing diets Furthermore, some fat in the diet makes for more palatability Fats are a source of fat-soluble vitamins Fats spare protein In animal studies certain fatty acids have been found necessary for growth, lactation, and proper skin condition Fats are the only source of these essential fatty acids

Question Should we attempt to restrict cholesterol in the diet?

Answer No rigid restriction seems necessary It has been well shown that alteration of dietary cholesterol from as little as 200 mg to as much as 1,000 mg per day does not affect the level of the cholesterol in the blood Practically speaking, these quantities cover a range that represents anything from no milk and no eggs to a quart of whole milk and two eggs

Question Do not we know that lowering the serum cholesterol level is a means of reducing the formation of atheromatous plaques?

Answer If this question had been phrased the other way, namely, that elevating the serum cholesterol level produces atheromatous plaques, we would have been tempted to say "yes" In animal studies it has been found that elevating the serum cholesterol level results in atherosclerosis, although thrombosis and infarction have not usually been produced in such animals Whether the high cholesterol levels cause the plaques, or whether both are the result of other factors, is not known In man, there is only indirect evidence, however, that an elevated serum cholesterol level causes atherosclerosis Nevertheless, myocardial infarction is more prevalent in men under 50 with elevated levels of cholesterol, and this fact certainly should be taken into account by the practicing physician, particularly when he is dealing with patients suffering from coronary artery disease or with those whom he determines to be in a more susceptible group We should be applying every reasonable hypothesis in the treatment of the patient when we do not know the specific answer, but in our thinking about diets for the public, we should keep in mind that, although the serum cholesterol level and atherosclerosis in man undoubtedly are interrelated, important details of this relationship are not understood

Question What is an elevated serum cholesterol level? How often should this level be measured, and should any other lipid measurements be made?

Answer To answer the last part first, one can say that the total cholesterol level of the serum gives as much (or as little) information for diagnosis, prognosis, and therapy of atherosclerosis for the individual as any other chemical measurement available today Additional lipid measurements are useful in research, but, as far as we know, they do not aid in taking care of the patient

Accurate and reproducible determinations of the serum cholesterol level can be obtained only with skill and care Total cholesterol levels show appreciable spontaneous variations that are usually unexplained These biological variations may be as much as plus or minus 20% Thus, not too much faith should be put in a single cholesterol value, particularly if it is an initial determination and seems 'out of line We would suggest that, if possible, the initial determination be followed by another, one to seven days later Patients on specific diet therapy might have total cholesterol levels determined monthly, and a yearly cholesterol level determination should certainly be a part of an annual health examination of all adults perhaps of adolescents as well

Now the first part of this question—what is an elevated cholesterol level? Scientifically speaking, we do not know To some extent, this question must be considered in terms of the age of the patient and certainly in terms of sex A paper from our laboratory has appeared in the April, 1957, issue of the *American Journal of Medicine*, dealing with the cholesterol levels in the serum of Americans It is based on studies on 1,920 adults (1,508 males, 412 females) who appeared healthy and fulfilled simple clinical criteria of normalcy,' particularly with regard to cardiovascular disease, and 273 men with definite evidence of myocardial infarction, 141 men with definite angina pectoris, and 23 women with evidence of myocardial infarction From these studies we might say that a serum total cholesterol value is elevated if it is above the mean of 240 mg for the man of 40 to 50 years who is apparently well, for the woman of that age, any value above 225 mg should be considered to be elevated

Because comparative studies with people of other countries where coronary thrombosis is less prevalent suggest that mean values of apparently healthy adults in this country may be high, it might be desirable if the values of serum total cholesterol for both sexes were lower It is interesting that if one sets the desired limits at one standard deviation below the means of the male coronary group in the age range 40 to 50 years one gets a value of 212 mg per 100 cc It makes better sense to dissociate oneself, so far as serum cholesterol levels are concerned, from a group of patients with known coronary artery disease than to be included in a group who appear well but may have latent disease An important difference may exist between cholestrol levels that are satistically "normal" and levels that are 'desirable "

Question If a patient has an elevated cholesterol level and is obese, what diet should be recommended?

Answer The hypercholesteremia and the obesity must both be considered, and they may or may not be related Weight reduction on any type of a well-balanced diet that supplies a deficit of calories is usually indicated for the obese patient The possibilities of treating hypercholesteremia by dietary means will be dealt with separately

Question Should "crash" diets be used to obtain quick weight reduction?

Answer Although the statement 'a screwball needs a screwball diet is facetious, it contains a germ of truth, and, we might add, such diets are usually recommended by 'screwballs" For reducing diets to be effective, they must be made up of foods that are palatable, available, can be afforded, and that provide adequate nutrition, also, the diets must be adhered to for a long time

Question If a patient has an elevated serum cholesterol, what diet should be recommended?

Answer If the 'patient' is an apparently healthy person in for a checkup, we would suggest the following alternative, using a consistent decrease in the total cholesterol in the serum as a measure of success

First of all, if weight reduction is indicated, any type of a well-balanced diet that is low in calories should be prescribed However, it is questionable whether a decrease in the serum cholesterol level that is induced by weight reduction can be maintained after caloric equilibrium has been reestablished A moderate increase in physical activity might be tried, such as walking half a mile two or three times each day In addition to weight loss and exercise, one might try a diet in which the fat is reduced to 25 to 30% of total calories Such a diet would entail a reduction of most of the visible fats This can be accomplished by trimming fat from meat, use of lean meats and smaller servings, more fish, and consuming less butter, margarine, whole milk, cheese (except cottage), bacon, and egg yolks It really is not known whether a diet in which the fat has been reduced to 25 to 30% of the calories will diminish coronary artery disease, although such a diet should result in a moderate weight loss for most people

Another possible dietary regimen would provide the accustomed 40 to 45% of total calories from fat and would emphasize the unsaturated fats that are good sources of essential fatty acids to the extent that they might supply about 25% of the fat calories, or 10% of the total calories We have found it difficult to increase the intake of essential fatty acids any more than this without using formula diets or specially devised foods Again, there is no good evidence that such a diet will lessen the incidence or degree of atherosclerosis, much less the prevalence of coronary artery disease

If the patient is acutely ill from one of the complications of atherosclerosis, therapy might include a very low fat diet—20% or less of the total calories from fat A formula-type diet containing a suitable vegetable oil as the sole source of fat might also be tried

Question What are unsaturated fats?

Answer The terms "saturated' and 'unsaturated apply to the fatty acids in fats Fats are combinations of glycerine and various fatty acids The latter are either "saturated" or 'unsaturated" depending on the number of double bonds in their carbon chains There are varying types of unsaturation referred to as "mono" or "poly" unsaturation Frequently, when the term "unsaturated fats" is used in discussions of this kind, one is thinking of certain "polyunsaturated fatty acids"

The fats in the American diet contain a large amount of unsaturated fatty acid, mostly in the form of oleic acid, which is monounsaturated Vegetable shortenings contain appreciable amounts of unsaturated fatty acid largely as the monounsaturated fatty acid, oleic acid The fatty acids found in cottonseed oil, soybean oil, and corn oil are mainly polyunsaturated acids, specifically the polyunsaturated acid known as linoleic acid These oils contain about 50% of this polyunsaturated acid Shortenings, margarines, and lard may contain a small amount or as much as 10 or 12% of linoleic acid The more saturated dietary fats such as butter fat, cocoa butter, coconut oil, and beef fat contain 1 to 3% linoleic acid Another source of fat in the diet is peanut butter It contains 20 to 25% linoleic acid, even if hydrogenated fat is also present to prevent separation

Conventionally, linoleic, linolenic, and arachidonic acids have been regarded as the "essential fatty acids," and all are polyunsaturated Linolenic acid is not very prevalent in any of our common edible oils Polyunsaturated acids are present in beef fat and lard and in certain marine fats and oils such as herring, cod, menhaden, salmon, and sardine Archidonic acid is present in all mammalian tissues, notably, heart, kidney, liver, and glandular tissues It is formed in the animal organism from linoleic acid, presumably by a mechanism involving vitamin B_6, and is regarded by some investigators as the functional essential fatty acid

Question Would it not be a good idea to limit the fats in the American diet to those that are polyunsaturated?

Answer We are not yet ready to point to one or two kinds of fats as being beneficial in the prevention of atherosclerosis By the same token one cannot point to certain fats as being harmful We are not talking about diets for specific patients Little work has been done on the effect of different types of fat in the normal diet over long periods of time As a result, we do not know whether a change in cholesterol level of any significant proportion could be obtained in the American population by dietary means This is an important point to establish, and large-scale controlled studies should be undertaken to answer this question

Question Is it possible that a diet high in polyunsaturated fatty acids could cause any ill effects?

Answer Any drastic changes in the accustomed diet could lead to unforeseen metabolic disturbances—a good reason to always be careful about recommending drastic changes in the diet until an abundance of convincing evidence is available on all points involved

Actually, there is some evidence from animal studies that a high intake of polyunsaturated fatty acids may deplete stores of vitamin E

Question Where does the cholesterol go when the total cholesterol level is reduced in the serum by various dietary means?

Answer Some animal studies suggest that body tissues other than blood are also decreased in cholesterol content There is no evidence that cholesterol in leaving the blood is increased in any body tissues Presumably, it is excreted, but certainly this point is not established

Question We hear much about the Bantu and his low-fat diet, how low in fats are these diets, and is this the major difference from American diets?

Answer Bantu diets, as well as diets from other peoples of the world, vary A R P Walker, of Johannesburg, who has probably studied the diet of the Bantu as carefully as anyone, states that they average 40 Gm of fat per day, providing 15% of the total calories More than half of this fat is 'hidden,' being contained in legumes and in the lightly milled cereal products that generally supply 50 to 90% of the calories These comments apply primarily to rural groups

There certainly are many differences other than fat in these diets Generally the Bantu-type diets are also low in animal protein and sucrose and high in fiber and starch, and the vitamin and mineral content may differ appreciably from American diets It is possible, and likely, that dietary differences other than fat may be involved in the problem of atherosclerosis and its complications

Question Is the intake of vitamin B$_6$ and protein important in planning a diet for a patient with atherosclerosis?

Answer So far as is known, any well-balanced diet will supply adequate amounts of vitamin B$_6$ and of protein, including good quality protein Protein quality and vitamin B$_6$ have come into the picture mainly because of experimental studies with monkeys and rats They have little specific clinical significance with regard to this problem in man as of today The same might be said for niacin Conceivably, diets high in linoleic acid may increase our need for vitamin B$_6$ Very-low-protein diets, as, for example, the "rice diet" which furnishes only 20-30 Gm of protein, usually causes a decrease in the serum total cholesterol level Whether this is because of the loss in weight that generally takes place on such a diet or because such diets are low in fat as well as in protein is not known

Question Is diet therapy the most important item in treating a patient for coronary artery disease?

Answer After the acute phase of the illness is over, diet therapy is certainly important Probably the greatest value of nutritional research in this area lies in the potential it holds for possible prevention or mitigation of this disease by dietary measures

Question Is there evidence that small quantities of unsaturated vegetable oils, particularly corn oil, can be added with profit to a diet containing a moderate amount of animal fat?

Answer There is little evidence that small amounts of corn oil added to a diet of ordinary foods containing moderate amounts of animal fat will result in a lowering of the cholesterol level, and there is absolutely no evidence that it will affect the regression of atherosclerosis or lessen the likelihood of the development of coronary artery disease

Question Although the common vegetable oils rich in linoleic acid may be hypocholesteremic, are they also thrombogenic' because they tend to neutralize the heparin-like substances in the blood?

Answer We know of no evidence that these oils are "thrombogenic' It has been reported that under certain conditions blood clotting is somewhat accelerated for a few hours after the ingestion of a meal rich in fat, regardless of the type of fat

Question Can you provide a week's menus of a diet that approximates 2,200 calories per day and in which about 30% of the calories are furnished by fat?

Answer A reduction of the fat to 30% of the calories represents a decrease of about one-fourth in the typical American diet The populations in some parts of the world where the incidence of coronary artery disease is very low receive only 10 to 15% of their calories from fat Reducing fat calories to 30% in the American diet, without a proportional increase in calories from other sources, should result in a decrease in the incidence of obesity and thus improve health from many viewpoints, perhaps including that of coronary artery disease However, this latter point is by no means proven The following menus assume small to average servings and no second helpings This is important, most important!

They average 70 Gm of fat, 90 Gm of protein, and 300 Gm of carbohydrate They supply adequate amounts of vitamins and minerals for average adults In calculating diets, one must take into account the small amounts of fat provided by bread and other constituents of the diet relatively low in fat No gravy is used, as it is almost impossible to estimate the fat content This means that pan gravy or whatever comes off steak or roast during the cooking, as well as thickened gravy or sauces, are not included in the menus Meat is trimmed of all visible fat before being served No foods are fried, but very small amouts of fat may be allowed to prevent sticking and dryness With careful planning, a small amount of butter or fat can be used, but generally not more than 3 pats of butter or other fat a day Vinegar, lemon, onion juice, spices, and herbs may help season vegetables and meats Salads of greens, tomatoes, and fruits may be on the menu for any lunch or dinner, and if a dressing is desired it should be one of oil and vinegar and used sparingly One teaspoon of sugar and one teaspoon of whole milk may be added to each cup of coffee or tea as desired Snacks are included, and, if a bedtime snack is desired, it is suggested that those who are reducing or having trouble maintaining their weight save their dessert for this snack

These menus will provide about 30% of their calories as fat If it is desired to increase the proportion of essential fatty acids in the diet and still keep the fat at 30% or less, skim milk can be substituted for whole milk, and more generous use of lean and low-fat meats such as veal, chicken and turkey, and fish can be allowed In addition to being relatively low in fat, these latter three foods also contain more of the essential fatty acids than most meats Jellies, jams, and cottage cheese may be used as spreads on bread

One Week s Menus of Diet that Approximates 2,200 Calories Daily and in Which About 30% of Calories are Furnished by Fat

Day 1

Breakfast
Prunes ¼ cup
Poached egg
Toast 2 slices
Butter 1 pat
Jelly 1 tbsp
Coffee or tea

Lunch or Supper
Grape juice cocktail 4 oz
Shrimp salad (½ cup shrimp 3 tbsp boiled dressing lettuce seasoning)
Melba toast 2 slices
Jam 1 tbsp
Pineapple sherbet (water)
Milk 1 cup
Tea or coffee

Dinner
Roast beef 4 oz
Boiled potato 1 medium
Peas 1 serving
Tomato aspic salad
Roll 1
Butter 1 pat
Angel cake 1 serving
Apricots 1 serving
Coffee or tea

Between Meal Snacks
Choice of one
Soft drink 1
Fruit juice 1 serving
Milk 1 cup
4 crackers or 2 plain cookies

Day 2

Breakfast
Orange juice 4 oz
Cereal 1 serving
Milk 1 cup
Toast 1 slice
Jelly 1 tbsp
Coffee or tea

Lunch or Supper
Bouillon
Cold roast beef sandwich with mustard
Sliced tomato
Strawberry shortcake (biscuit and berries)
Milk 1 cup
Coffee or tea

Dinner
Tomato juice cocktail
Broiled halibut 1 pat butter (for cooking)
Parsley potato
Butter 1 pat
French style green beans 1 serving
Grapefruit and orange salad
Roll 1
Jelly 1 tbsp
Jello
Tea or coffee

Between Meal Snacks
Choice of one
Soft drink 1
Fruit juice 1 serving
Milk 1 cup
4 crackers or 2 plain cookies

Day 3

Breakfast
Grapefruit juice 4 oz
Cereal 1 serving
Blueberry muffin 1
Jam 1 tbsp
Milk 1 cup
Coffee or tea

Lunch or Supper
Fruit salad plate (pear apple grapefruit orange banana strawberry)
Cottage cheese 3 tbsp
Toast 2 slices
Butter 1 pat
Plum jam 2 tbsp
Coffee or tea

Dinner
Consomme 1 serving
Saltines 3
Lean roast leg of lamb 3 oz slice (3" x 2¾" x ⅜")
Parsley buttered potato 1 serving
Glazed curried peach ½
Brussel sprouts 1 serving
Cloverleaf rolls 2
Butter 1 pat
Jam 1 tbsp
Lime ice ½ cup
Coffee or tea

Between Meal Snack
Choice of one
Soft drink 1
Fruit juice 1 serving
Milk 1 cup
4 crackers or 2 plain cookies

Day 4

Breakfast
Orange juice ½ cup
Cereal 1 cup
Milk 1 cup
Sugar 1 tsp
Egg
Toast 1 slice
Jam 1 tbsp
Coffee or tea

Lunch or Supper
French onion soup with 4 saltines
Sardine sandwich
Tomato 1 medium stuffed with cottage cheese ¼ cup in lettuce cup
Angel cake 1 piece
Coffee or tea

Dinner
Shrimp cocktail (6 shrimp 4 tbsp sauce)
Broiled chicken ¼ medium broiler

Between Meal Snack
Choice of one
Soft drink 1
Fruit juice 1 serving

Day 4 (Continued)

Rice ¾ cup with butter 1 pat
French style green beans ½ cup seasoned with thyme green onion
Endive lettuce grapefruit salad with oil and vinegar dressing (1½ tsp oil)
Rolls 2 small
Guava jelly 2 tbsp
Fruit
Coffee or tea

Milk 1 cup
4 crackers or 2 plain cookies

Day 5

Breakfast
Sliced orange
Cereal 1 cup
Milk 1 cup
Sugar 1 tsp
Toast 1 slice
Strawberry jam 1 tbsp
Coffee or tea

Lunch or Supper
Roast veal 3 oz
Spaghetti ½ cup
Tomato sauce
Frozen peas ½ cup
Italian bread 1 slice
Jelly 1 tbsp
Peaches ¼ cup
Milk 1 cup
Coffee or tea

Dinner
Lean baked pork loin 4 oz seasoned with mustard Worcestershire sauce
Baked potato 1 medium with 1 tbsp sour cream and chives
Broccoli ½ cup
Lettuce salad with vinegar
Small roll 1
Marmalade 1 tbsp
Lemon chiffon pie 1 serving
Coffee or tea

Between Meal Snack
Choice of one
Soft drink 1
Fruit juice 1 serving
Milk 1 cup
4 crackers or 2 plain cookies

Day 6

Breakfast
Grapefruit ½
Soft cooked egg 1
Whole wheat toast 2 slices
Strawberry jam 1 tbsp
Coffee or tea

Lunch or Supper
Breast of chicken ¼ of large
Mushroom caps on toast triangles (oil 2 tsp for cooking)
Broccoli with lemon
Celery hearts and radishes
Sponge cake
Milk 1 cup
Coffee or tea

Dinner
Tomato bouillon
Saltines 2
Roast beef 4 oz
Baked potato
Butter 1 pat
Squash
Tossed salad with lemon juice
Parkerhouse roll jelly
Meringue filled with cherries
Coffee or tea

Between Meal Snack
Choice of one
Soft drink 1
Fruit juice 1 serving
Milk 1 cup
4 crackers or 2 plain cookies

Day 7

Breakfast
Large grapefruit ½
Poached egg
Toast 2 slices
Jam 2 tbsp
Coffee or tea

Lunch or Supper
Tomato juice cocktail 4 oz
Saltines 2
Toasted turkey sandwich
Sweet pickles 2 small
Radishes 2
Celery hearts
Fruit
Milk 1 cup
Coffee or tea

Dinner
Jellied consomme
Saltines 4
Broiled swordfish 4 oz with lemon wedge
Parslied buttered potato 1 medium with 1 pat butter
Asparagus 1 serving
Mixed green salad with 1 tbsp sour cream dressing
Rolls 2 small
Honey 2 tbsp (or 2 tbsp jam or marmalade)
Melon balls ⅔ cup
Coffee or tea

Between Meal Snack
Choice of one
Soft drink 1
Fruit juice 1 serving
Milk 1 cup
4 crackers or 2 plain cookies

This reduction of the more saturated fats permits greater use of cottonseed, corn, and soya oils in salad dressings and cooking and the use of peanut butter as a spread, without increasing the fat beyond 30% of the caloric intake

Summary

All of the current excitement over dietary fat and atherosclerosis is over the results of relatively limited studies These include the experimental production of atherosclerosis in animals, short-term studies of changes in blood lipids on persons generally on formula diets, and epidemiologic and statistical studies done as well as can be done but about which there are some misgivings While these are stimulating advances in research and may be good clues, they may not be entirely relevant to coronary thrombosis, the leading cause of death among adults in this and many other countries

Although most epidemiologists would agree that the differing incidences of coronary artery disease in various population groups is related to a differing mode of life, it has not been conclusively established that dietary factors, and specifically total fat intake, are of primary etiological importance

There is no doubt that patients transferred from a self-selected diet to a purified formula-type diet high in linoleic acid will usually display a decrease in serum cholesterol level This apparently is sustained for as long as the formula diet is fed However, experience with such formula diets, although accumulating rapidly, *still must be considered limited*, both in numbers of subjects studied and in duration Further, these formula diets are not of practical importance for the public at large Interestingly, those that have been most effective have not been low in fat—rather, they have been high in fat

Little information is available concerning the supplementation of ordinary American diets with oils rich in essential fatty acids In the light of current information it does not seem justified to recommend drastic changes in either quantity or type of fat in the diet of the general population on the assumption that such changes will lessen the incidence of coronary artery disease However we should remain alert to the possibility that appropriate recommendations may be desirable at some future time

In general, adults who are not overweight, without any family history of early death from heart disease, and with relatively low levels of serum cholesterol (in the range of 175 225 mg per 100 cc) need make no changes in their diet assuming they already consume a variety of foods providing a well-balanced diet Obese individuals with cholesterol levels that are not elevated might well reduce their body fat content on any type of well-balanced diet Obese individuals and nonobese individuals with consistently elevated cholesterol levels have somewhat more reason to attempt to lower them, particularly if there is a family history of early death from cardiovascular disease Individuals who have had a "coronary are really in the class of "sick patients," and recommendations for them should be on an individual basis and should come only from their doctor

What are the dietary changes that can be tried by individuals who may fit into some of the above categories, that is, individuals who may be particularly susceptible to coronary artery disease? First, weight loss on any type of a well-balanced diet, that is, 'cutting down, not cutting out' with regard to food intake Second, reduction of the calories derived from fat so that fat provides 25 to 30% of the calories rather than the customary 40 to 45% Third, either of the above procedures but with a definite attempt to substitute for the saturated fats in the diet—butter, whole milk, some meat fats, and perhaps margarines and vegetable shortenings—those unsaturated fats that are good sources of the essential fatty acids, particularly linoleic acid Fourth, a diet of our usual fat intake, 40 to 45%, but with much of the fat rich in the essential fatty acids

Examples of common food fats high in essential fatty acids are cottonseed oil, corn oil, soya oil, and various nut oils The oils and fat of some fish, such as herring, menhaden, salmon, sardine, and cod, are good sources of polyunsaturated fatty acids but are not common in the American diet

Margarines and vegetable shortenings contain some linoleic acid They also contain some isomers of linoleic acid There is little evidence, however, that these isomers act as antilinoleic compounds, particularly with regard to cholesteremia Far more research needs to be done with these substances, as well as with other fats, and their relation to the problem of atherosclerosis Mention may also be made of the possibilities of increasing the linoleic acid content of the common animal fats by including generous amounts of polyunsaturated fats in the ration of the animal The same could be said for vegetable shortenings through technical changes in their manufacture, for hydrogenation is a controllable process and, within limits, the amount of essential fatty acids can be varied

In the light of all of these developments, the physician has a real opportunity to practice good preventive medicine with regard to our leading cause of death First, to reassure the public and prevent mass hysteria for drastic changes in our dietary, and second, to guide his patients, depending on their individual status, along dietary patterns that consider advances in research

If for no other reason than the avoidance of obesity there will probably be a trend in this country to less rich diets," which means less calories in the diet Because fats are such a concentrated source of calories, a moderate reduction of fat intake will result in a generous reduction in calories Since most of us enjoy eating, there will be room' in our diets for foods of lower caloric content These foods might well be cereals and grains and their products, and vegetables and fruits—foods, incidentally that are commonly used by many groups of people thoughout the world who have a lower incidence of coronary thrombosis than we do

As a final word, we should like to affirm that nutritional researches in this important area of health are most promising and we are enthusiastic about them But, we think that such enthusiasm should be directed toward further research, to get the many answers we do not have, rather than toward suggesting changes in our accustomed diets, when we are not too sure at this time if, or how, they should be changed

The researches referred to in this paper that were done at the Department of Nutrition, Harvard School of Public Health have been supported in part by a series of grants from the National Institutes of Health, the Albert and Mary Lasker Foundation, the John A Hartford Memorial Fund, the Nutrition Foundation, and the Fund for Research and Teaching of the Department of Nutrition, Harvard School of Public Health

HYPOPHYSIAL GROWTH HORMONE

Recent reports on the chemical properties and physiological action of growth hormone preparations made from human or monkey pituitary glands provide striking evidence that the apparent ineffectiveness of growth hormone preparations of bovine or porcine origin in primates may be due to chemical differences in growth hormone derived from various species

Acromegaly was shown to be associated with enlargement of the pituitary gland by Minkowski in 1887, and by 1909 a number of investigators had shown that hypophysectomy in animals led to a retardation of growth [1] More convincing evidence of the existence of a pituitary growth factor was forthcoming, in 1921, when Evans and Long [2] injected saline extracts of ox anterior pituitary glands into rats and found they increased in weight and grew more rapidly than littermate controls Shortly thereafter, Smith [3] observed that rats that had undergone hypophysectomy would resume growth if injected with anterior lobe extracts In 1944, Li, Evans, and Simpson [4] succeeded in making a growth hormone preparation of high purity from ox anterior pituitary, and, in 1948, Wilhelmi, Fishman, and Russell [5] isolated a crystalline product with similar physicochemical characteristics Using a radically different chemical procedure, Raben and Westermeyer [6] in 1951 isolated from pig pituitaries a growth hormone preparation with solubility properties different from those of bovine growth hormone

While the physiological effects of growth hormone of bovine or porcine origin can readily be demonstrated in the smaller laboratory animals, results in man [7] and in monkeys [8] have been consistently equivocal The view that this apparent ineffectiveness might be due to chemical differences between growth hormone isolated from various species was supported by the reports of Wilhelmi [9] and of Li and Papkoff [10] Wilhelmi demonstrated chemical and physical differences between growth hormone from ox, sheep, pig, horse, and fish pituitaries and noted that growth hormone isolated from fish pituitaries was effective in fish but not in rats, while bovine extracts were effective in both fish and rats Li and Papkoff isolated growth hormone preparation from human and monkey pituitary glands and demonstrated physicochemical differences between these preparations and growth hormone preparations of bovine origin

Evidence that the chemical differences observed by Li and Papkoff and by Wilhelmi may be associated with differences in physiological activity has been presented by Knobil and co-workers [11] and by Beck and his associates [12] Knobil and co-workers isolated from monkey glands a preparation rich in growth hormone as shown by assays in rats This preparation administered to monkeys that had undergone hypophysectomy caused an elevation in fasting blood sugar level, decreases in insulin sensitivity and glucose tolerances, and repair of the costochondral junction, and returned nitrogen retention to prehypophysectomy levels Further, Beck and his associates administered to a person with dwarfism of pituitary origin, human and monkey growth hormone prepared by Raben [13] Both extracts resulted in increased weight and marked retention of nitrogen, potassium, phosphorus, and calcium, while impairment of the glucose tolerance curve was demonstrated with human but not with monkey growth hormone These studies have greatly advanced our understranding of the relationship between the chemical structure and physiological activity of growth hormone preparations

ORGANIZATION SECTION

REPORTS ON HEALTH AGENCIES

Two recent reports, one published by a committee of the American Medical Association and the other by the National Better Business Bureau, Inc., place new emphasis on the expanding role of voluntary health agencies in the health and economy of the nation. The bureau surveyed 284 businesses constituting a cross section of American industry; its report is based on replies from 158 of the firms and on information from 26 national health agencies. The A. M. A. publication is on "Suggested Guides to Relationships Between Medical Societies and Voluntary Health Agencies." According to the bureau's poll:

—The average company contributes to twice as many national health agencies as it did five years ago.

—Nearly all national business firms are supporting these agencies through direct contributions and through United Funds and Community Chests.

—Figuring the rising number and amount of contributions to more and more such health agencies, the total cost of health services in the United States today is estimated at 13 billion dollars. This is said to cover hospital care, preventive medicine, research, food and drug regulation, sanitation, and public information.

One out of every $11 contributed to 12 of the national health agencies during their last fiscal year came directly from business—a total of $10,500,000, according to the bureau's report, and business gave another 4 million dollars indirectly through federated fund drives. More than half of the companies making direct contributions to national health agencies stated that "the effectiveness of the agency's over-all program" was the principal reason for support.

More specifically, the survey indicated that the chief motive of nearly three out of four corporations was the "relation of the cause to the need of society." Personal interests of executives, many of whom serve in individual fund drives, also was given as a significant reason. "Effect of disease on the economy" was attributed by 41 of the 158 firms figuring in the study.

In this latter connection, the report cites a "staggering" production loss from the effects of alcoholism on employees—352 million man-hours lost. The bureau's survey quotes Dr. Marvin A. Block, Chairman of the A. M. A. Committee on Alcoholism, in his estimate that chronic alcoholism in the United States directly affects 20 million people who are families of the alcoholics.

A. M. A. Committee Report

Medical societies and voluntary health agencies have mutual obligations, according to the set of "suggested guides" published this month by the American Medical Association Committee on Relationships Between Medicine and Allied Health Agencies, headed by Dr. Sidney J. Shipman of San Francisco. "Physicians and medical societies, concerned as they are with the diagnosis and treatment of disease and the promotion of health, are expected by the public to support these voluntary efforts," according to the committee statement. But it adds that, although most such agencies merit support from the profession, "the medical society, in some instances, might press for changes in policy or procedure."

The committee cautions physicians that, while they should support voluntary health agencies, they should do so "within their sphere of interest, and recognize whether their role is as official representative of the medical society, interested physician, or private citizen."

The "suggested guides" state: "Medical societies should participate and when desired give agencies advice and counsel on the medical and civic aspects of community needs. Voluntary health agencies should establish liaison with the medical society and frame their programs to conform to sound medical practice."

(A complete draft of the "Suggested Guides," as approved by the committee June 2, 1957, pending final action by the A. M. A. Board of Trustees, and as sent to medical societies last month, is published on page 1933 of this issue.)

SPECIAL COMMITTEE ON INFLUENZA

The following report has been compiled from late data furnished to the American Medical Association's Special Committee on Influenza by the Communicable Disease Center of the Public Health Service, U. S. Department of Health, Education, and Welfare. Progress reports on Asian influenza will be transmitted to the profession regularly as long as there is a possibility of an epidemic.

Harold C. Lueth, *Chairman*

CURRENT STATUS OF ASIAN INFLUENZA

Sporadic cases of influenza-like illness continue to be reported among civilian groups. Great difficulty has been encountered in gaining some quantitative measure of these cases. School absentee records are currently not available because of the summer school recess. Furthermore, influenza "listening posts" maintained by states in large industrial concerns are presently not in operation because of the season. It is hoped that methods for estimating community influenza morbidity in various areas will soon be in operation

Further outbreaks of influenza-like illness have occurred among migrant workers from Mexico in Michigan and Indiana Asian strain has been confirmed in the Michigan outbreak Influenza has also appeared in two crowded labor camps in New York state Such episodes had previously been reported from California labor camps

An explosive outbreak of influenza has caused 10 of the 12 schools in a Louisiana parish to be closed Intensive investigation of the situation is presently in progress

Impressions of increased respiratory illness have been noted from Florida, Texas, Roanoke, Va, and New Orleans Hospital personnel in a hospital located in the last-named city seem to have been particularly affected

Isolations of Asian strain have now been reported from several South American countries including Chile and Columbia Asian strain isolated in Miami had been obtained from Chilean airline crews

At present no extensive influenza outbreaks are in progress Nevertheless report of sporadic cases are increasing This appears to be a real increase for this season and not merely increased attention to febrile respiratory disease

Vaccine Information

Monovalent influenza vaccine will be available for civilian use beginning sometime in September The principle of a vaccine containing only Asian strain virus has been accepted in order to facilitate production and to provide as large a volume as possible for immunization Present requirements call for an antigenic virus mass of 200 CCA units per milliliter The six manufacturers producing vaccine will concentrate production efforts on the monovalent material By mid September it is expected that 8 million doses will have been released, half of which is earmarked for the armed forces A production goal of 60 million doses by Feb 1, 1958, is the present estimate of supply potential

Although a polyvalent preparation containing an Asian strain of virus remains the ideal vaccine, the above recommendation appears to be a necessary and reasonable expedient After one injection of influenza vaccine, antibodies are detectable in about 10 days If results are comparable with previous influenza vaccine experience, subsequent protection may be expected for the duration of the influenza "season" Antibodies may be detected in a slightly greater number of persons if a second injection is given at a three or four-week interval

No formal federal system of vaccine allocation is presently contemplated A plan of immunization priorities, however, has been suggested by the surgeon general of the Public Health Service As vaccine becomes available, priority for immunization should be given to 'those whose services are imperative for the care of the sick and to essential workers in the communication, transportation, and utility industries About 12 million doses will be needed for these groups It is hoped that they will receive the earliest supplies of vaccine in order forestall serious impairment of vital services in the event of a major influenza epidemic this fall

COUNCIL ON MEDICAL SERVICE

THE OLDSTER AND HIS DOCTOR

Wingate M Johnson, M D, Winston Salem, N C

This is the first of a series of papers on various aspects of aging Each paper has been prepared for the Committee on Aging by an authority in the field When completed, the series will be published in booklet form

In medical practice at its best, no one factor is more important than the proper relation between doctor and patient This factor assumes particular significance in dealing with older patients So much of pediatric practice consists of giving routine immunizations, recording weights and measurements, and prescribing formulas for various ages that a well trained nurse can take over a great many of the pediatrician's duties The doctor can usually stay in the youngster's good graces by giving him a lollipop or bright piece of cardboard after the nurse has done the dirty work of puncturing his skin

The oldster, however, is not so easily managed The years have taught him caution in bestowing his confidence, and his diseases are apt to be of a chronic or recurrent nature A satisfactory relation with his doctor is most important to the patient's well-being and peace of mind Such a relation is most often one that has developed over many years The advice of a doctor who is himself well matured is often more acceptable to the elderly patient than is that of a younger man It is

---

Professor of Clinical Medicine and Director of the Private Diagnostic Clinic Bowman-Gray School of Medicine of Wake Forest College

Members of the Committee on Aging are Drs H B Mulholland, Chairman, Charlottesville, Va Edward L Bortz Philadelphia, Henry A Holle, Austin, Texas, Wingate M Johnson, Winston-Salem, N C, Theodore G Klumpp, New York, Frederick C Swartz, Lansing, Mich and Cecil Wittson, Omaha Committee Staff Mr George W Cooley, Secretary, and Mr Herbert B Norton, Research Assistant frequently true, however, that a young doctor who really likes people—and no man who does not should be a family doctor or an internist—can win the confidence and even the affection of his older as well as his younger patients (Witness Rev Morgan, M D, and his favorite patient, Melissa) Whether a doctor be young or old, he will need special reserves of patience and equanimity in dealing with many of his elderly patients

Attitudes Toward Aging

The oldster s attitude toward the aging process may be resentful, resigned, or realistic The first two attitudes are hardest to deal with The resentful patient is apt to be immature in spite of his years Often he has been spoiled in childhood, accustomed to getting what he wanted by temper tantrums Later, as a parent and spouse, he—or often she—has achieved the same aim by the technique of domineering or of clinging Such individuals need understanding and a certain amount of sympathy—but not the sort of sympathy that makes them a prey to self-pity and encourages their childish resentment against life

The resigned oldster makes no effort to keep up with current events or to contribute his best efforts to worthy causes He is apt to use his age as an excuse to decline invitations to participate in social or community affairs He is quite willing to accept financial support as a debt owed by the government or his children Such people need to be encouraged to find something useful to do and to maintain an interest in living

The realistic person accepts aging as a natural phenomenon and looks for the good in it as well as for the bad He learns, without adopting a "Pollyanna" attitude (familiar to the older generation), that old age has its compensations Some of these will be pointed out later

The doctor who deals with many older patients will learn to recognize their reactions to age and will often be able to help them develop the right attitude In order to win their confidence, he will need to be sympathetic, sincere, and sensible His sympathy should be of the practical sort which does not expend its force in pitying the patient but which looks for means to relieve his doubts and fears He will need, to use a modern term, empathy as well as sympathy

His sincerity should be so evident that he will not need to proclaim it with a trumpet The oldster instinctively senses the doctor's attitude If it be patronizing or impatient, the patient will almost certainly withdraw into his shell It is necessary to make him feel that, for the time, he has the doctor's undivided attention

The older patient also wants his doctor to be sensible in discussing his problems whether they be physical, mental, or even spiritual He will resent evasive answers or sugar-coated reassurance that all is well when he knows that all is not well The average intelligent oldster appreciates a clear explanation of such conditions as hypertrophic arthritis and angina pectoris or even of a small cerebral thrombosis It is important, however, for the doctor to select his words with care, avoiding such dread terms as "hardened arteries, cancer, and "stroke " Thewlis[1] has given an excellent discussion of the proper use of words in his classic work The Care of the Aged,' under the section entitled Logotherapy

The doctor himself should look for the good things about maturity and help the oldster to appreciate them Among these are the relative rarity of rheumatoid arthritis or rheumatic fever, freedom from migraine, better resistance to infectious diseases, and, for women, release from the nuisance of menstruation

The physician might also point out to his elderly patients that the material comforts of modern living, while deplored by some Spartan-minded ascetics, make living more pleasant for all ages Older people should be encouraged to accept such innovations as air conditioning, electric blankets, and oil and gas heat (to say nothing of indoor plumbing) instead of clinging to their time-honored inconveniences Not the least of the blessings of this modern age is the more sensible clothing worn by both sexes Certainly the lighter apparel adopted by men in hot weather is more conducive to a long and comfortable life than the tall hats, frock coats, and high collars which were once the hallmark of the professional man By adapting his own wearing apparel to sensible modern styles, the physician who has the respect and confidence of his older patients may influence them to place comfort over custom in the matter of clothes

Physical Aspects of Geriatric Practice

Geriatrics might be given the same definition as pediatrics— general practice with an age limit ' It is doubtful, however, that many medical men will ever label themselves as geriatricians and limit their practice exclusively to older patients To do so would largely defeat the purpose of geriatrics, which is concerned as much with preventing the ravages of age as with treating them Preparation for age should begin in the prime of life, and to this end every general practitioner and internist should try to train his middle-aged and even his younger patients to cultivate proper habits of eating, sleeping, exercise, recreation, work, and mental hygiene

All men and women past middle age should be encouraged to let their birthdays remind them that it is time for another complete physical examination On a patient's first visit for such a health inventory, sufficient time should be allowed for a careful history and physical examination The history should not only include a recital of the presenting symptoms and an adequate system review but should go into the patient s living and working conditions, his habits, and his attitude toward his family and associates as well as theirs toward him Subsequent appointments can be made much shorter, since it will be necessary only to fill in the gaps between visits On the first examination a chest x-ray and an electrocardiogram should be made for a permanent record but these need not be repeated on subsequent visits unless some indication arises

The interview should conclude with detailed advice about diet, exercise, and sleep, and possibly about the patient s relations with his family and associates One of the most important bits of advice that can be given most patients at middle age or beyond is to keep their weight at its optimum level It might be wise to caution the patient that a favorable health inventory does not guarantee a full year of untroubled operation for the human machine He should be encouraged to come back between annual visits if any marked departure from his normal status occurs

Psychological Aspects of Geriatric Practice

One of the most important services the doctor can render the oldster is to help him make the necessary psychological adjustments to aging Many of the most unpleasant traits of adolescence and old age have a common basis—the desire to belong As Stuart Chase said in 'The Road We Are Traveling," Men want to feel that they are a part of a living community, that they have a place in it which other people recognize" The adolescent wants to achieve recognition as a useful member of society, the oldster wants to retain that recognition The doctor can help the oldster's morale by showing a genuine interest in him and in his environment

One of the greatest problems the aging person must face is that of retirement It is not surprising that many men who are forced to retire from their lifelong occupations while still vigorous and alert become victims of mental depression The doctor who is himself able to keep at work when long past the customary retirement age should not be blind to the fact that relatively few of his nonprofessional contemporaries are so fortunate As a citizen, the doctor should use his influence to protest the arbitrary custom of requiring a man to give up his work at a fixed age, regardless of his physical and mental fitness As a physician, however, he must help his older patients meet the changes in their lives which retirement brings

Often associated with retirement is the problem of financial dependence and the prospect of widowhood and physical disability Whenever feasible, it is usually best for members of the older generation to live apart from the families of their children or grandchildren—either in their own homes, apartments, or rooms, or in the homes and hotels which are becoming recognized as a necessity for older people in modern society If it is actually necessary for a family to take an elderly relative into the home, it is best to have a distinct understanding at the very beginning concerning the division of responsibility and authority He—or she—should not be allowed to become a petty tyrant nor be made to feel helpless by too much attention For his own sake, it is best to allow him to do as much as possible for himself and for others Here, again, the doctor who has gained the confidence of his oldster patient is in a better strategic position to talk frankly with him about his relations with his younger relatives and possibly to suggest the advisability of living in his own quarters

It is the doctor's privilege as well as his duty to help his older patients make the best possible adjustment to their advancing years In this task he has the assistance of Nature's beneficent provision for changing one's viewpoint with advancing years Except at the climacteric, adjustments to increasing age levels are usually made so gradually as to be almost imperceptible

Some years ago I formulated seven "rules of conduct" for my own use and have found that some or all of them could be used to advantage in helping my oldster patients and friends to grow old with a reasonable degree of complacency These rules—or suggestions—are as follows

1 Recognize that the mind should be at its best when a person is about 40 years old and should continue to be efficient to the age of 70 or more The pathologists have shown that organic changes in the brain do not necessarily parallel mental changes The mind which is properly trained does not lose its elasticity, and constant use of the brain helps to keep it efficient

2 Avoid becoming an 'old fogy by frequent association with young people Prepare for occasional shocks, but try to understand their viewpoint

3 Learn to delegate authority and to unload responsibility upon younger shoulders There is an advantage in partnerships in which the enthusiasm of youth is balanced by the judgment of maturity

4 Cultivate wide interests Learn new uses for the hands and brain, and exchange more strenuous amusements for others less arduous As A C Benson[2] has said, "One ought to grow older in a tranquil and appropriate way to be perfectly contented with one's time of life amusements and pursuits ought to alter naturally and easily, and not be regretfully abandoned'

5 Keep in touch with old friends and make new ones Dr Samuel Johnson once said, 'If a man does not make new acquaintances as he advances through life he will soon find himself alone A man sir, should keep his friendship in a constant repair"

6 Cultivate equanimity—the mental poise that keeps one from being unduly elated by good fortune or depressed by bad news and that teaches one to take fortune's buffets and rewards with equal thanks[3] It is important to keep a proper balance between emotion, which furnishes the driving power for the human machine, and reason, which corresponds to the steering gear and the brakes

7 Cultivate the habit of looking forward rather than backward This advice may seem to conflict with Osler's admonition to live one day at a time, but it really does not Planning for tomorrow is often part of today's task, but sighing over yesterday accomplishes nothing

Finally, since personal experience is always more convincing than mere theorizing, let me offer the testimony of two philosophers who lived centuries apart More than 2,000 years ago Plato[4] quoted the reply of the aged Cephalus to the question, "Is life harder towards the end, or what report do you give of it?' "Old age has a great sense of calm and freedom, when the passions relax their hold, then we are freed not of one mad master only, but of many He who is of a calm and happy nature will hardly feel the pressure of age, but to him who is of an opposite disposition youth and age are equally a burden"

The other philosopher is Dr Francis M Pottenger,[5] who in the final chapter of his autobiography, published in 1952, said "My 80 years do not worry me To be sure, I would like again to have the keenness of youth On the other hand, I would miss the mellowness of age, the store of experience which guides me in my every movement and act I have tried not to live too much in the past, but to be alert to the problems of the future This I have accepted as an antidote to aging It does not prevent the years from rolling by but it does prevent that fear of the future which otherwise might make one unhappy in the twilight of life ”

Summary

To most patients, a happy relationship with a good doctor is more important in the later than in the earlier years of life Since preparation for old age should begin in the prime of life, it is desirable that this relationship be established early in senescence Maturity in the doctor offers some advantages, although it is not essential if he is really interested in the problems of older patients and genuinely likes people

The attitude of the oldster toward the aging process may be resentful, resigned, or realistic The doctor can help to foster the correct attitude in his aging patients by being sympathetic, sincere, and sensible He should be interested not only in the oldster's physical condition but in his environment his interests, and his emotional status The doctor needs to be truly the oldster s guide, philosopher, and friend

MEDICINE AND THE LAW

MEDICAL-LEGAL COOPERATION

Charles S Rhyne, Washington, D C

Both of our professions are faced with tremendous problems and almost immeasurable duties and responsibilities from the great new scientific, economic, and social changes of our day These great changes have created new tasks for us which exceed in magnitude all that we have thus far known They present a tremendous challenge and grave responsibilities for us all Communications have shrunk nations to neighborhoods We live in a physically indivisible world International affairs control our domestic planning more and more The seemingly constant international crisis overhangs us all in everything we do Such is the world in which we live Such is the picture against which we must plan together to do those things we should do jointly

It takes no great imagination to appreciate some of the fields of endeavor that challenge our joint initiative in this era of change One has only to lift up his eyes and mind from his patients and clients and participate in the day-to-day affairs of our social and political life to know that there are many problems in our rapidly changing world which we can help solve together I pass over the new and challenging problems out on the frontiers of these new developments to mention only three—three that have been with us for some years now but to the solution of which I believe our professions can make a major contribution These are juvenile crime, mental illness, and alcoholism

Juvenile Crime

We are witnessing a tragic increase in the growth of juvenile crime throughout the nation In refusing to dignify this matter as juvenile delinquency, I deliberately consider the federal and state reports showing an alarming increase in serious crimes of youth from all strata of our society Unless this trend is reversed we could witness a problem that could rot and destroy the very substance of our democracy

In many instances, we all know, punishing youngsters as adults only results in developing more hardened criminals ready to prey on society when their initial term at reform school is completed On the other hand, it is sickening to see violent crimes of youth treated by some judges as minute and unmeaningful things dismissed with mild and meaningless warnings I am certain that many ramifications of this whole matter lie squarely within the province of responsibility of the bench and bar We are charged with the duty of writing and enforcing the laws We also have the duty of studying and analyzing the law to recommend improvement in it so as to meet and solve the new and developing social problems I am not certain we have fully met our responsibility with this problem But I believe this is a medical problem also—possibly not in the cut and bruise division, but certainly within that province of medical knowledge that deals with the mind and with the matters of a person's adjustment to his social environment Medicine can inform us how to treat youthful offenders, how to ferret out those who are in need of help, how to properly rehabilitate those in need of guidance Through the science of medicine we can be given insight into the proper legal cure to combat this great

---

President-elect American Bar Association

Read before the House of Delegates at the 106th Annual Meeting of the American Medical Association, New York, June 3, 1957 national problem I think maybe both our professions have been somewhat lax in assuming our responsibilities We need to press upon the authorities our peculiar abilities in this field and demonstrate to them the possible contributions we can make

Mental Illness

Mental illness is another problem we must lick together In my own community, the District of Columbia, over 3,000 mental cases were admitted to the District of Columbia General Hospital alone in 1956, over 5,000 was the average daily census of District patients at St Elizabeths Hospital in the same year, and over 10,000 school children were adjudged at the same time to be suffering from some form of emotional disorder How do we reach these people, how can society govern their conduct to make them profitable to themselves and others, and how are they to be cured—these are your responsibilities, and they are mine

Recently our Court of Appeals held that a man had a constitutional privilege to be represented by a lawyer at a mental committing inquest Prior to this decision it was customary to proceed without the presence of an attorney We all recognize the burden that this is apt to place upon commitment procedure, but I am sure you will agree that a man has as much right to his lawyer in these proceedings as he does in a court of law It would be vastly unfair, almost cruel, to permit confinement of this nature in a procedure devoid of the protection of legal rights

This court decision will necessarily call for a greater degree of cooperation, study, and understanding by the attorney and the physician in the District of Columbia I am hoping that the local chapters of our organizations will be able to effect a program of mutual cooperation and help so that we will be able to work effectively together We can anticipate an even greater interest in this field in years to come As our knowledge expands, as our problems increase, as our duties become more clear, we shall need each other more and more, and I am hopeful that we will be able to work together on a solution for this awesome problem

Alcoholism

And lastly, let me mention briefly the problem of alcoholism—a social, medical, and legal problem not confined to the District of Columbia alone, I am assured We all recognize that our laws are antiquated and presently ineffective to meet the increasing burden of this challenge Clearly the present policy of "keeping them off the streets" and giving chronic alcoholics short ineffective prison terms hardly faces the problem at all and certainly does not solve it And the result is a great increase in the incidence of crime due in part to alcohol, broken homes, and drunken and reckless driving resulting often in needless slaughter, these are just examples of the results of this illness They do emphasize the staggering proportions of the problem and the really frightful alternative facing us Either the law recognizes a different approach or we shall continue as we are in a situation not satisfactory to anyone If there is a medical solution then we should proceed full speed to its discovery I feel probably the answer lies somewhere between, partly revamping the legal attitudes and partly a redeveloping of medical understanding and treatment But we accomplish little by talking about it We must do something and it is clear, at least it is clear to me, that we must do something together

Joint Undertakings

I think the first step must be taken on the local level I think the leaders of the bar associations and the medical associations in each community across this nation must take greater steps to work out more effectual programs for joint undertakings Good laws can only be made through a proper understanding of all the aspects of the problem In the three problems I have noted, the medical aspect is of great importance, but unless an avenue be found for the lawyer, the judge, and the legislator to hear you, to understand you, and to welcome your advice and recommendations, they will necessarily proceed without the benefit of your knowledge This would be tragic It is a tragedy that has occurred before, but must not occur again

Let me conclude by expressing my appreciation of the fine work that we have been able to accomplish together so far on the Jenkins-Keogh self-employment retirement income legislation We have enjoyed working on this bill with Dr James R Reuling, the Chairman of your Committee on Legislation, and believe that there is excellent chance to secure passage of this legislation

This noon I had the privilege of witnessing the premiere showing of the second movie in the series "Medicine and the Law, created through the joint efforts of our two associations The title of this latest film is "The Doctor Defendant " The very favorable reception of the first film, "The Medical Witness," was most encouraging We feel sure that the series of six films will be a major contribution toward improving medical-legal cooperation in a most vital area of our relationships We are all indebted to the W S Merrell Company for making these films possible

We wish to express our appreciation to C Joseph Stetler, Director of your Law Department, for his excellent cooperation in the making of these films and upon the whole of the newly inaugurated program of cooperation between our professions The medicolegal committees of our two associations are exploring all possible areas for cooperation I am sure much benefit will come to both of our professions from this joint endeavor

Medicine and law, while at times a mystery one to the other, are in effect inseparable instrumentalities bound together Together we can constitute strength in the progress of our democracy Working together we can meet the challenge that is ours in our changed and changing world I assure you that we in the legal profession stand ready to work with you in every possible way for the advancement of the welfare of the people of our nation and of the people of the world

COMMITTEE ON RELATIONSHIPS BETWEEN MEDICINE AND ALLIED HEALTH AGENCIES

SUGGESTED GUIDES TO RELATIONSHIPS BETWEEN MEDICAL SOCIETIES AND VOLUNTARY HEALTH AGENCIES

The following committee report was approved June 2, 1957, pending final action by the Board of Trustees Copies of this draft have been sent to state and county medical societies for comment

GEORGE COOLEY, *Committee Secretary*

Voluntary health agencies are an American institution They have developed with the past half-century Starting with the National Tuberculosis Association in 1904, the agencies at the national, state, and local level, devoted wholly or in part to health promotion, are now numbered in the hundreds

Physicians and medical societies, concerned as they are with the diagnosis and treatment of disease and the promotion of health, are expected by the public to support these many voluntary efforts Each agency strives for medical approval and wants to count physicians among its members

Nature of Voluntary Health Agencies

Agencies concerned with health vary widely in organization, objectives, means for attaining objectives, fund raising methods, membership, and relationship of groups at national, state, and local levels However, even with these variations, not infrequently, their likenesses are more notable than their differences Their principal characteristics are (1) a voluntary, nongovernmental association of citizens, with (2) a common goal or interest, usually the prevention and control of some disease or infirmity, which (3) gathers voluntary contributions, gifts, memorials, and memberships, and (4) expends its resources in ways decided by the governing body of the agency, most often for public and professional education, medical and basic science research, and in a number of instances the underwriting of medical care

The kinds of community agencies interested in health, including the voluntary health agency, can be classified into the following types

1 The local subsidiary of a national agency concerned with a single disease condition which uses its funds primarily for health education of the public, possibly for research and, in some instances, to provide medical care Examples of such organizations are the National Tuberculosis Association, the American Cancer Society, and the National Foundation for Infantile Paralysis

2 The local subsidiaries of national agencies concerned with a certain group of people having common problems which may be the result of a variety of related diseases Among these are such agencies as the National Society for Crippled Children and Adults and the National Association for Mental Health

3 Local subsidiaries of national organizations whose primary interest is civic betterment but who from time to time become interested in preventive medicine or provide medical care for specific short-term problems Among these are the national civic organizations such as Rotary, Lions, and Kiwanis, business groups such as the Chamber of Commerce, academic fraternities and sororities, and women's organizations

4 Locally organized groups, which may or may not be affiliated with a national program or agency, such as the auxiliary groups supporting local hospitals or clinics, infant welfare societies, local health councils, and social agencies in the fields of family welfare, adoptive placements, family counseling, and various youth activities

5 Community coordinating groups such as welfare councils, health councils, and community chests and similar groups engaged in community planning, in administrative research, and in the distribution of money gathered through federated giving

The larger and better known voluntary health agencies have now become an accepted part of our culture They have made available contributions to education and research Many of the smaller, more recently developed agencies are equally reliable and at least as valuable However, even though these agencies have medical direction at the national and state level and are accepted by the medical associations at these levels, an effort must be made toward mutual understanding at the local level, including medical direction

Voluntary Agency Evaluation

The medical society is dedicated to maintenance of health in the communities its members serve It, therefore, has an interest in and an implied responsibility for citizen groups who profess a similar dedication Any agency that collects dues and contributions so that it may conduct health education, research, and service for the prevention of disease and the rehabilitation of the crippled, therefore, becomes an object for medical society consideration

The medical society approach to any agency should be friendly, since these agencies intend to promote health through support of sound medical practice It should also be constructively critical, since occasionally uninformed enthusiasts can make mistakes which distort even well-planned policy The evaluation that a local medical society makes of a local voluntary agency must answer at least the following questions 1 What relation does the local voluntary agency have to a similar state or national agency? Is it a subsidiary chapter, affiliate, or independent competitor? 2 Why was it started in this community? Who started it and what interests are promoting it? 3 Are the purposes and stated objectives of the agency desirable, in conformity with those of the parent agency, medically justifiable, and possible of attainment by the program proposed by the agency? 4 Does the agency respect local customs for collecting money in the drive for memberships and contributions? 5 Is the fund goal realistic when related to community needs and the anticipated over-all program of the agency at the local, state, and national levels? 6 Is the cost of fund raising and administration comparable to similar expenses of other agencies in the community and reasonable in relation to expenditures for the stated objectives? 7 Are the educational and promotional materials medically correct, ethically presented, in good taste, and educationally sound? 8 Can the expenditures allocated for research be justified by local disease problems as well as by national research needs? 9 How are expenditures for service related to local needs for such service and to the established community programs for medical care?

Medical Society Obligation to Voluntary Agencies

Most voluntary health agencies warrant medical society participation and support of their policies In the interests of enlisting public support for the promotion of health, medical societies have an obligation to help agencies conform to good practice Most voluntary health agencies would be more susceptible to modification of their practices by participation, support, and advice from the county medical society than to adverse criticism and opposition Medical societies may offer assistance in many ways, among which are to (1) arrange liaison by making available medical society representation on the governing board of the voluntary health agency, (2) make available an advisory service to the agency on policy and practice decisions that involve matters relating to medicine or physicians, (3) cooperate with the agency in planning its program in relation to community health needs and evaluation of how well these needs are being met, and (4) encourage medical society members to stimulate public support of the agency and its program

Voluntary Agency Obligation to the Medical Society

Every voluntary health agency, or organization concerned with matters of medical care and health promotion, has certain obligations to the community in which it operates and to the physicians and their medical society who provide the health service in that community To enjoy the confidence of the medical society and merit its continuing support, voluntary health agencies need to meet certain obligations, among which are that (1) its basic policies regarding medical care and preventive medicine should conform with the policies and practices acceptable to the medical profession in that particular community, (2) the governing board of the voluntary agency should in all instances provide an opportunity for representation of the medical profession designated by the county medical society, (3) problems involving medical policy and practice should be considered in consultation with appropriate medical society committees, and (4) the program of the agency, including the collection and disbursement of its funds, should conform to community custom and be related to the community's needs and the over-all program of the agency at the local, state, and national level

Role of Physicians in Relation to Voluntary Health Agencies

The individual physician plays four separate but related roles when he becomes affiliated with a voluntary health agency or other voluntary organization concerned with a phase of preventive medicine or medical care 1 He may be delegated as an official representative of his medical association, in which case he acts for the medical society expressing the consensus of his colleagues 2 He may be called on by an agency to serve it as a physician in ways suggested by his specific professional interest 3 Because of his interests, he may seek membership on his own accord and become active in an agency's program 4 As a private citizen interested in his community, and regardless of his profession, he may use a health agency as the medium for public service

The obligations of these roles are quite different It is therefore imperative that both the physician and the voluntary health agency he is serving recognize the particular role being played The representative of a medical society designated to serve as an official channel of communication has a different status than a private physician serving an agency as an individual A physician selected by a voluntary agency to serve on its board has no authority to speak for the local medical society unless granted that authority by action of the medical society

This point is quite confusing to agencies who are not acquainted with interagency representation Physicians who are close to interagency personnel should explain that, though physician membership on a board of directors is desirable and is to be encouraged, such members do not represent the medical society unless they have been named by the medical society as its official spokesman

All voluntary health agencies depend on membership dues and voluntary contributions They also must have the contributed time of volunteer workers interested in promoting the agency's objectives Since the community looks to physicians for endorsement of a health agency, the physician is obligated to speak well of an agency whenever possible He also will feel obligated to support with time and money those agencies in which he has personal interest

Summary

The voluntary health agency is now a recognized community function, and most agencies merit medical society support of their objectives, though the medical society, in some instances, might press for changes in policy or procedure Medical societies and voluntary health agencies have mutual obligations Medical societies should participate and when desired give agencies advice and counsel on the medical and civic aspects of community needs Voluntary health agencies should establish liaison with the medical society and frame their programs to conform to sound medical practice Physicians should support voluntary health agencies within their sphere of interest and recognize whether their role is as official representative of the medical society, interested physician, or private citizen

MEDICAL NEWS

GEORGIA

Cardiovascular Research—A grant from the National Heart Institute, U S Public Health Service, of $300,297 has been awarded to William F Hamilton, Ph D , professor of physiology, and Raymond P Ahlquist, Ph D , professor of pharmacology, University of Georgia School of Medicine, Augusta, to continue a postgraduate cardiovascular research and training program for the next six years Program trainees for the year 1957-1958 include the following Colin Fell, Ph D , Wayne University, Detroit, Dr Alceo Barrios, Faculty of Medicine, Buenos Aires, Argentina, Dr Evan Lindberg, Grace-New Haven Hospital, New Haven, Conn , Dr Ali Mehrizi, Children's Hospital, Detroit, and Charles R Wallace, D V M , Alabama Polytechnic Institute, Auburn, Ala

KENTUCKY

Society News—New officers of the Kentucky Radiological Society are Dr David N Shapiro, Louisville, president, Dr James S Rich, Lexington, vice-president, and Dr Robert H Akers, 1405 West Broadway, Louisville 3, secretary-treasurer ——The Kentucky State Medical Association has moved its headquarters office to the Medical Arts Building, 1169 Eastern Parkway, Louisville 17 The new phone number is GLendale 4-6324

Dr Dodd Appointed "Distinguished Professor of Pediatrics"—Dr Katherine Dodd has been appointed "distinguished professor of pediatrics," University of Louisville School of Medicine, effective this month Dr Dodd is retiring as chairman of the department of pediatrics, University of Arkansas, Little Rock, which she has served for the past five years Previously, Dr Dodd taught at the University of Cincinnati for 9 years after teaching pediatrics at Vanderbilt University, Nashville, Tenn , for 18 years As "distinguished professor," Dr Dodd will be free of administrative detail and able to bring to bear her experience in the teaching of clinical pediatrics on the undergraduate students and the 21 house officers of the department

MARYLAND

Appoint Chairman of Ophthalmology Department—Dr William M Hart, Bethesda, has been appointed chairman of the department of ophthalmology of the Sibley Memorial Hospital of American University Dr Hart is clinical associate professor of ophthalmology, Georgetown University, Washington, D C, and special lecturer in physiology He is also consultant in ophthalmology to Walter Reed Army Hospital Previously he was chief, department of ophthalmology at the Clinical Center, National Institutes of Health, Washington, D C

MASSACHUSETTS

Society News—The Massachusetts Society of Anesthesiologists has elected the following slate of officers president, Dr Benjamin Etsten, Boston, vice-president, Dr James H Buskirk, Cambridge, and secretary-treasurer, Dr John H Tucci, Brockton

Personal—Dr Benedict F Massell, research director, House of the Good Samaritan, assistant clinical professor at Harvard Medical School, and chief, rheumatic fever division, Children s Medical Center, Boston, has received the American Heart Association award of merit in recognition of service in advancing the association's national program to reduce death and disability from diseases of the heart and circulation

Revise Clinical Curriculum at Tufts—The *Tufts Medical Alumni Bulletin* for June reports that the faculty of Tufts College Medical School, Boston, has accepted the following revisions for the academic year 1957-1958 (1) Establishing the major inpatient clinical clerkships in medicine, surgery, and pediatrics in the third year, (2) Lengthening the clinical clerkships in medicine and surgery from 8 to 12 weeks, (3) Further reducing the number of whole class didactic lectures, (4) Inaugurating a program of seminar teaching in groups of 16 to 20 students under the immediate direction of moderators selected from the clinical faculty, and (5) Establishing a continuous 14-week elective period in the fourth year

MICHIGAN

Establish State Experimental Biology and Medicine Section—A Michigan section of the Society for Experimental Biology and Medicine has been established The following officers have been elected chairman, Dr Walter J Nungester, University of Michigan, vice-chairman, Joseph Meites, Ph D , Michigan State University, secretary-treasurer, Burton L Baker, Ph D , University of Michigan, and committeeman-at-large, Dr Conrad Lam, Henry Ford Hospital, Detroit

It is planned that the section will meet three times a year, with the location of the meetings rotating between Ann Arbor, East Lansing, and Detroit For information write Joseph Meites, Ph D , Michigan State University, East Lansing, Mich

NEW JERSEY

Winners of Hospital Contest—Dr Alfred Zettner, resident, department of pathology, Mountainside Hospital, won the contest sponsored by the hospital medical staff for members of the house staff, who were asked to submit original papers on medical subjects He received an award of $125 Dr Thomas J Degnan won second prize of $100, and Dr William V Chokas, resident, department of medicine, received third prize of $75 The title of Dr Zettner's paper was 'The Relation of the Oxygen Hemoglobin Equilibrium to the Hematocrit" Two of the winning essays have been accepted for publication in medical journals

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities new hospitals, education, and public health Programs should be received at least three weeks before the date of meeting

NEW YORK

Graduate Fortnight Shortened—For the past 29 years the New York Academy of Medicine has held an annual Graduate Fortnight This year the program will be contracted to a Postgraduate Week of five days, Oct 7-11, with daily evening lectures, afternoon panel meetings and a scientific exhibit The title of the 1957 postgraduate week program is "Research Contributions to Clinical Practice" The purpose of the postgraduate week is the continuing education of graduate physicians For information write Dr Robert L Craig, Secretary, Postgraduate Week Committee, New York Academy of Medicine 2 E 103rd St, New York City 29

Personal—Dr Helen E Elliott has been appointed deputy assistant commissioner of the State Department of Mental Hygiene Dr Elliott, former assistant director (clinical) at Central Islip State Hospital, will serve as assistant to Dr Henry Brill, assistant commissioner in charge of the division of research and medical services ——Dr Luigi Pellegrini is a new member of the medical staff of Eaton Laboratories, Norwich, N Y Dr Pellegrini served three years in the Army Medical Corps during the Korean War, attaining the rank of captain Before going to Norwich he was a resident physician at Fordham City Hospital, and was on the medical staff of New York City's department of correction, Riker's Island

Dr Elmer Hess Heads Selective Service Committee—Dr Elmer Hess, of Erie, recent president of the American Medical Association, has been appointed by President Eisenhower as chairman of the National Advisory Committee to Selective Service on the Selection of Physicians, Dentists and Allied Specialists He succeeds Dr Howard Rusk, of New York City, who has held the post since the committee's formation in 1950, when the doctor draft went into effect The committee advises on the induction of medical and dental officers in the armed services

Dr Hess served in the Army Medical Corps in World War I in France He has made several missions abroad for the government He left July 31 on an inspection tour of Air Force medical facilities in Europe and North Africa for the Surgeon General of the Air Force

Surgical Appointments—Drs Robert D Whitfield and William A Milner have been appointed sub-department heads in the department of surgery at Albany Medical College Dr Whitfield, an associate professor of surgery, will head the sub-department of neurosurgery Dr Milner becomes head of the sub-department of urology Both Dr Whitfield and Dr Milner had earlier served as acting heads of these sub departments Dr Whitfield is a member of the staff of many area hospitals and is a diplomate of the American Board of Neurological Surgery and a fellow of the American College of Surgeons Dr Milner, a member of the faculty at Albany Medical College since 1931, is president-elect of the northeastern section of the American Urological Association Dr Milner is a fellow of the American Board of Urology and is a consultant urologist at a number of area hospitals

Study of Retarded Persons—A grant of $120,000 to New York University for a two-year study of the factors determining the institutionalization of retarded persons has been announced The study, which begins this month, will be conducted by Gerhart Saenger, Ph D, director of the school's research center and a member of the university's psychology department The goal is to find out whether institutionalization constitutes the best possible solution for different groups of retarded persons now usually sent to institutions To obtain data that may lead to improvement in services for the retarded, a staff of 50 professional social workers attached to the research center of the Graduate School of Public Administration and Social Services will make an investigation of records of institutions, public and private social agencies, schools, and special clinics A major part of the study will consist of interviews with about 1,000 parents of retarded persons between the ages of 1 and 25 to get their reactions toward services they have received

New York City

Appoint Assistant Dean—Arthur V Jensen, Ph D, has been appointed assistant dean at New York Medical College, Flower and Fifth Avenue Hospitals Dr Jensen has been associate professor in the department of anatomy at the college for the past four years, and he will continue in that position He has been faculty member of the staffs of the following institutions Institute of Neurology of Northwestern University School of Medicine, Chicago, University of North Carolina School of Medicine, Chapel Hill, and Adelphi College, Garden City, L I, and for two years he was a member of the Committee for Post-Graduate Medical Education of the University of North Carolina

Appoint Physical Medicine Administrator—Dr John L Enyart, who retired as U S Naval Surgeon, Medical Branch, Supreme Headquarters Allied Powers Europe (NATO Forces) Paris, in June, has been appointed administrator of the Institute of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center Dr Enyart served at the Royal Naval College Hospital, Dartmouth, England, in 1943-1944 He was staff surgeon Naval Forces, France, 1944-1945 and executive officer of U S Naval Hospital, Philadelphia, 1945-1946 Dr Enyart served with the National Advisory Group to Nationalist China from 1946 to 1948 and was commanding officer of the U S Naval Hospital, Newport, R I, from 1953 until his appointment to NATO

NORTH CAROLINA

Personal—Dr John H Ferguson, head, physiology department, University of North Carolina School of Medicine, Chapel Hill, has been awarded the doctor of science degree by his alma mater, the University of Cape Town South Africa It was awarded to Dr Ferguson for his research in the field of blood coagulation and hemorrhagic diseases ——Dr Edwin P Hiatt, associate professor of physiology, University of North Carolina School of Medicine, Chapel Hill, has accepted a research position as chief of the acceleration section and consultant to the biophysics branch of the Aero-Medical Laboratory at Wright-Patterson Air Force Base near Dayton, Ohio

Grant for Teaching Films—A $27,275 March of Dimes grant has been made to Duke University, Durham, to continue its production of motion pictures for teaching anatomy to medical students, occupational therapists, and other persons involved in the treatment of poliomyelitis Underway in the Medical School since 1951, the project has been supported by a series of March of Dimes grants now totaling $210,392 J E Markee, Ph D, James B Duke Professor of Anatomy and director of the project, said that the films make possible a more effective teaching program in anatomy without unduly increasing the load on teachers or the time assigned to this subject Trainees in orthopedics, pediatrics, anesthesiology, and other medical specialties also make use of the films, which are available on a loan basis for use by professional schools and associations

OHIO

Cincinnati Eye Bank—For less than a year an eye bank has been established at the Cincinnati General Hospital, closely associated with the University of Cincinnati Medical School and the Department of Ophthalmology Since its organization, more than 50 eyes have been donated and about 30 corneal graft operations performed The purposes of the eye bank are (1) to establish sources of supply of salvaged eyes, corneal tissue, and vitreous fluid and to provide the means for their collection, preparation, storage, and redistribution to hospitals and surgeons for corneal and retinal detachment operations, (2) to extend and encourage, by teaching and research, the knowledge and skill required to perform corneal graft operations, (3) to carry out research work on eye disease, particularly that resulting from corneal damage, glaucoma, and retinal detachment The eye bank is supported entirely by private donations for its over-all operation Executive director of the eye bank is Mr Benn C Budd

Academy of General Practice Meeting—The seventh annual scientific assembly of the Ohio Academy of General Practice will be held Sept 18-19 at the Franklin County Veterans Memorial, Columbus The program includes the following topics by out-of-state speakers

The Art of Treatment with Tranquilizing Drugs, Dr Frank J Ayd Jr, Baltimore
Cervical Biopsies in Office Practice, Drs Malcolm L Barnes and George S Allen, Louisville, Ky
The Allergic Patient, His Problems Office Diagnosis and Treatment (Emphasis on Bronchial Asthma), Dr Nathan E Silbert, Lynn, Mass
The Irritable Child, Dr James L Dennis, Oakland, Calif
Gynecological Disease in Adolescents and Children, Dr Edward Allen Chicago

Guest speaker at the banquet Sept 18 will be Dr Edward H Rynearson, Rochester, Minn, who will speak on Both Doctors and Patients are Human Beings " Technical exhibits are planned and a special ladies' program has been arranged For information write the Ohio Academy of General Practice, 209 South High St, Columbus 15, Ohio

OKLAHOMA

Society News—The Oklahoma Society of Anesthesiologists has elected the following officers president, Dr William B Renfrow, Oklahoma City, president-elect, Dr Carl Guild, Tulsa, and secretary-treasurer, Dr Lawrence Stream, Oklahoma City

Appoint Head of Radiology Department—Dr Gus R Ridings, formerly associate professor of radiology, University of Mississippi Medical Center, has become the first full-time head of the department of radiology at the University of Oklahoma School of Medicine, Oklahoma City His appointment now gives the school seven clinical departments with full-time directors Dr Ridings has served as instructor in radiology at the Vanderbilt Medical School, New Orleans He had also received resident training in radiology at the University of Michigan Hospitals, Ann Arbor Dr Ridings will continue his research dealing with certain bone abnormalities

PENNSYLVANIA

Personal—Dr William N Parkinson, dean, Temple University School of Medicine and vice-president of the university in charge of medical affairs, received an honorary degree of doctor of laws at the June commencement exercises of the Jefferson Medical School ——Dr Morton J Oppenheimer, head, department of physiology, Temple University School of Medicine, received an honorary degree of doctor of science at the Ursinus College commencement exercises

Alvarenga Prize Awarded—On July 14, the College of Physicians of Philadelphia awarded the Alverenga prize for 1957 to Dr William C Stadie, professor emeritus, research medicine, University of Pennsylvania, for his major contributions to our knowledge of carbohydrate metabolism " The Alvarenga prize was established by the will of Pedro Francisco DaCosta Alvarenga, of Lisbon, Portugal, an associate fellow of the College of Physicians of Philadelphia, to be awarded annually by the college on the anniversary of the death of the testator, July 14, 1883

Conference on Nutrition—A conference on nutrition in relation to disease will be held Sept 30, at the College of Physicians of Philadelphia Floyd S Daft, Ph D, director, National Institute of Arthritis and Metabolic Diseases, Bethesda, Md, will speak on "Relationship Between Hormones and Nutrition" Dr Edward H Ahrens Jr, of the Rockefeller Institute of Medical Research, New York, will speak on 'Fat Metabolism in Relation to Cardiovascular Disease—Atherosclerosis" The conference is sponsored by the Commission on Nutrition of the Medical Society of the State of Pennsylvania, the Philadelphia County Medical Society and the National Vitamin Foundation Dr Michael G Wohl and Dr Robert S Goodhart will be chairmen at the evening session

TEXAS

Personal—Dr Lawrence M Shefts, of San Antonio, has been to the Far East on a 40-day tour of Army medical activities as consultant in surgery to the Army Surgeon General He arrived in Tokyo June 15 to begin his tours of inspection and lectures to professional groups in Japan, Korea, and Okinawa

Dr Haley Honored—Dr John C Haley was named 'Distinguished Professor Emeritus of Anatomy" at a luncheon on the occasion of his retirement from the faculty of Baylor University College of Medicine, Houston A plaque was presented to him in appreciation of 30 years of service to the university A graduate of the College of Medicine in 1927, Dr Haley served successively from 1927 to 1957 as assistant, assistant professor, associate professor, and chairman and professor of the department of anatomy He will continue as secretary-treasurer of both the Baylor Medical Alumni Association and the Baylor Medical Foundation Three of Dr Haleys four sons are graduates of Baylor College of Medicine The fourth son is an attorney in Waco

House of Representatives Praises Dr Spies—The A M A Washington office reported that the House of Representatives on July 23rd passed a concurrent resolution expressing the gratitude of Congress and the American people to Dr Tom D Spies for his medical achievements, including contributions to human nutrition Dr Spies, a native of Texas, was given the A M A's distinguished service award at the recent annual meeting in New York He is head of the department of nutrition and metabolism at Northwestern University Medical School, Chicago, and director of the nutrition clinic at Hillman Hospital in Birmingham, Ala The House resolution, introduced by Speaker Sam Rayburn, cited Dr Spies' work in the fields of earlier and better methods of diagnosis and treatment on nutritional deficiency diseases

Anatomy Research—The department of anatomy and biochemistry, Baylor University College of Medicine, Houston, recently received $80,000 from the U S Public Health Service to further their research programs Half the sum was designated for equipment and remodeling during the first year, with the remaining amount to be used for traineeships and summer fellowships to supplement the present program An additional $37,800 will be granted for each of the two subsequent years The objective is to train anatomists and biochemists by providing an opportunity for medical students to obtain training which might serve to recruit them for teaching and research positions The grants will also enable the departments to attract postdoctoral and senior research fellows in cancer biology and biochemistry and to train research assistants and technical personnel for positions in cancer research

UTAH

State Association Meeting—The 62nd annual scientific session of the Utah State Medical Association will be held Sept 5-7 at the Hotel Utah, Salt Lake City The presidential address will be given by Dr James Z Davis The program includes the following two symposiums Non-toxic Disease of the Thyroid, moderated by Dr Phillip B Price, dean, University of Utah, School of Medicine, and Can Every Doctor's Office Be a Cancer Screening Clinic?, moderated by Dr Emil G Holmstrom, head, department of obstetrics and gynecology, University of Utah School of Medicine, Salt Lake City The featured speaker at the presidential banquet Sept 5 will be Dr Gunnar Gunderson, president-elect, American Medical Association A special feature of the program will be the showing of the films, "The Doctor Defendant," and "The Medical Witness," with special guests, members of the Utah State Bar Association Panel discussions, exhibits, and other meetings are planned For information write Mr H Bowman, Executive Secretary, Utah State Medical Association, 42 S 5th East St, Salt Lake City, Utah

VIRGINIA

Society News—The following officers of the Virginia Academy of General Practice have been installed Dr Malcolm H Harris, of West Point, president, Dr W Linwood Ball, Richmond, president-elect, Dr Fletcher J Wright Jr, Petersburg, vice-president, Dr Russell G McAllister, Richmond, secretary, and Dr William A Young, Richmond, treasurer

WEST VIRGINIA

Personal—Dr Rezin D Stout, of Grafton, has been reelected for a two-year term as mayor of that city The City Council reappointed Dr Karl H Trippett as health officer for the fiscal year ending June 30, 1958

Rural Health Conference—The 10th annual Rural Health Conference, sponsored by the West Virginia State Medical Association, will be held at Jackson's Mill, Oct 1 The program has been arranged by the chairman of the Rural Health Committee, Dr Charles E Staats, of Charleston, in consultation with representatives of farm groups, the Agriculture Extension Service, and the State Department of Health Theme of the conference will be "Changing Patterns' Discussion groups will consider problems of the aging, insurance and hospital costs, mental health, and health hazards Two panel discussions will follow the luncheon to be served in the Mount Vernon Dining Hall For information write the West Virginia State Medical Association, Box 1031, Charleston 24

Plan University Teaching Hospital—The contract for the construction of the new teaching hospital for the Medical Center at West Virginia University has been executed by representatives of the University The total cost will be $13,172,000, and it is expected that the entire project will be completed in January, 1960 About a million and a half dollars of Hill-Burton Funds were involved in the transaction University officials received notice that on July 1 approval had been granted by the surgeon general, paving the way for the actual execution of the contract July 3

If the hospital is completed in January, 1960, patients can be admitted not too long thereafter so that junior students will be able to begin clinical work in September of that year If the schedule that has been arranged can be followed, the first class at the new four-year school will be graduated in June, 1962

Appoint State Health Director—Dr William B Rossman, of Charleston, has assumed his duties as director of the new State Department of Mental Health Dr Rossmann has been engaged in the practice of psychiatry and neurology in Charleston since 1946 He served as part-time director of the State Department of Health s Bureau of Mental Hygiene from 1947 to 1952 He is a diplomate of the American Board of Psychiatry and Neurology and is a member of the Kanawha Medical Society, and the West Virginia State Medical Association Dr Rossman will attempt to organize all state institutions on a similar basis regarding their professional policies, fiscal operations, and community services The bill setting up the new Mental Health Department was passed by the State Legislature during the closing days of the session in 1957 Under the new law, the director of the new Department of Health will appoint the superintendents of the mental institutions at Barboursville, Huntington, Lakin, Spencer, and Weston He will also name the superintendent of the West Virginia Training School at St Marys

WISCONSIN

Personal—Prof Joshua Lederberg, medical genetics department, University of Wisconsin Medical School, Madison, and Mrs Lederberg left Aug 1 for a trip to Australia They will both be traveling as Fulbright Scholars and will lecture at various points en route to Melbourne, where they will attend a symposium on bacterial and virus genetics Prof Lederberg will be working with Prof Frank M Burnet at the Walter and Eliza Hall Institute of Medical Research in Melbourne Dr Burnet was Slichter Professor at the University of Wisconsin Medical School a few years ago

Endocrine Award to Dr Mueller—Dr Gerald C Mueller, associate professor of oncology, University of Wisconsin Medical School, Madison, has been named as recipient of the 1957 Schering award of the Endocrine Society The award comprises a cash grant of $2,500 and is presented annually to a scientist who has made a notable contribution in the field of endocrinology The Endocrine Society was organized in 1918 to help stimulate interest in the study of internal secretions and to collect and disseminate literature on this subject Dr Mueller plans to study the biosynthesis of intracellular particulates He plans to devote six months at the Max-Planck Institut fur Virusforschung in Tubingen, Germany, to the study of virus reproduction and the metabolic interaction of the virus particle with the host cell In addition, he will visit with European scientists and discuss problems of endocrinology and cell physiology with them

GENERAL

Influenza in Russia—Dr Albert Sabin of the Children's Hospital Research Foundation, Cincinnati, recently returned from visiting a number of virological laboratories in the U S S R He was informed by virologists and epidemiologists there that an outbreak of influenza occurred last winter in Vladivostok and subsequently spread to Moscow and other places in the Soviet Union It was reported that the disease was typical of mild influenza In several affected areas, the laboratory findings indicated the outbreak was caused by influenza D (Sendai virus) Dr Sabin did not ask for the strains, but attempts are now being made to obtain them

Committee for Research in Blindness—A National Committee for Research in Ophthalmology and Blindness was recently formed by representatives from the four national ophthalmic societies the American Academy of Ophthalmology and Otolaryngology, the American Medical Association, Section on Ophthalmology, the American Ophthalmological Society, and the Association for Research in Ophthalmology The committee plans to stimulate interest in ophthalmic research and to cooperate with and act as an advisory group to all persons and agencies interested in blindness, the prevention of blindness, vision, and research in the basic disciplines of ophthalmology For information write Dr Frank W Newell, the University of Chicago, 950 E 59th St , Chicago 37

Maurice Husik Prize—Dr William D Stewart, of Vancouver, Canada, has become the first recipient of the Maurice Husik prize for his investigative work while with the department of dermatology and syphilology of New York University Post-Graduate Medical School, New York City Dr' Stewart was the senior investigator and, with Dr Victor H Witten, co-author of work on "Measurement of X-radiation Received by the Gonads During Dermatologic Therapeutic X-radiation Techniques" Dr Maurice Husik, for whom the prize was named, has been on the staff of the New York Skin and Cancer Unit for 25 years During this time patients established a fund to provide treatment for indigent patients In July, 1956, the Maurice Husik prize was established

Fracture Association Meeting—The American Fracture Association will hold its 18th annual meeting in El Paso, Texas, at the Hotel Cortez, Sept 30 Oct 2 Twenty-five papers will be presented at the general sessions Roundtable luncheons planned for Sept 30 will include Avoidance of Pit Falls in Fracture Therapy,' "Maxillofacial Fractures,' and 'Fractures of the Head and Neck of the Humerus" Discussion periods will follow the formal presentations Guest speaker at the meeting will be Dr Dana M Street, who will speak on 'Supplemental Fixation in Medullary Nailing of the Femur' A motion picture, 'Effective Use of External Internal Fixation in Fractures, Basic Procedures and Safeguards,' will be presented by Dr Philip T Holland, Bloomington, Ind Scientific and Commercial exhibits are planned The annual banquet will be held Oct 1 For information write Dr W Compere Basom, Chairman, American Fracture Association, 520 Montana St, El Paso, Texas

Radiology Awards—The National Academy of Sciences-National Research Council has announced the award of eight research grants, two fellowships and three scholarships, totaling $68,000 by the James Picker Foundation The awards were made on recommendation of the committee on radiology of the academy-council The foundation began its program of grants and fellowships in 1950 to foster reasearch and broaden the scope of radiology Foreign recipients of grants in radiological research include Dr Erling Hammer-Jacobsen, University Hospital of Copenhagen, Dr Albert Jutras, Hotel-Dieu Hospital, Montreal, and Dr Samuel Schorr, Hadassah University Hospital, Jerusalem Scholarships went to Dr James E Bauer, University of Missouri Medical Center, Dr Eugene C Klatte, Indiana University Medical Center, and Dr William J Ruddenham, University of Pennsylvania School of Medicine The fellows are Dr Alfred J B Palubinskas, University College Hospital, London, and Dr Anssi Pekka Soila, University of Turku, Finland

Awards for Research in Aging—Awards for research on the problems of aging have been presented by the Ciba Foundation on recommendation of a panel with Prof F G Young, Cambridge, England, as corresponding member Sixty-two papers were considered from 22 countries The two highest awards were presented to Dr Hedwig Saxl, Leeds, England, for his papers 'Physiological Significance of the Reaction Between Elastin and Elastomucase in Relation to the Production of Clearing Factor'", and Dr G F Wilgram, Toronto, Canada, "An Aetiological Concept of Atherosclerosis Based on Experiments in Rats' Other winners included Dr Robert J Boucek, Miami, Fla, Dr B T Donovan, London, and Dr J J van der Werff ten Bosch, Leiden, (jointly), Dr R F Hellon, Oxford, England, Dr H G Isler, Montreal, Canada, Prof L Haranghy, Budapest, and Dr Patricia Lindop, London The awards are being offered again in 1958, the closing date for entries being Jan 1, 1958, and information may be obtained from the Ciba Foundation, 41 Portland Place, London, W 1

Dr Mallamo Wins Annual Golf Tournament—Dr Joseph T Mallamo, of Fairmont, Va, won the American Medical Golfing Association's championship for 1957 in a playoff match with Dr Gilbert Bayne at the Westchester Country Club, Rye, N Y, during the annual meeting of the American Medical Association Drs Mallamo and Bayne posted a low gross of 74 over the "difficult west course' of the Westchester Club More than 150 doctors competed in the 41st golf tournament At the annual banquet Dr Paul S Wyne, of San Francisco, was installed as president of the association, succeeding Dr Joseph Corr, of New York City Other officers are Dr James McLaughlin, of Philadelphia, president-elect, Dr John Growdon, of Kansas City, first vice-president, and Dr Vincent Larkin, of New York City, second vice-president

The 1958 tournament will be held at the Olympic Country Club in San Francisco, Dr Wyne announced The 1957 tournament committee was under the chairmanship of Dr James T Daniels

Northwest Industrial Health Conference—The fourth annual Pacific Northwest Health Conference will be held Sept 9-10 at the Hotel Multnomah, Portland, Ore Conference topics include employment of the injured and the handicapped and industrial health problems in the transportation industry The program includes the following papers and speakers

Practical Aspects of Getting the Injured Worker Back to Work, Dr Henry Kessler, Kessler Institute of Rehabilitation, West Orange, N J
The Older Worker in Industry—Including Planning for Retirement, Dr James H Sterner, Eastman Kodak Company, Rochester, N Y
Medicine—A Full Member of the Industrial Health Team, Dr Dwight H Murray, past-president, American Medical Association, Napa, Calif

The conference is opened to physicians, dentists, business executives, and persons in allied professions Registration fee is $10 00 For information write Dr Ralph R Sullivan, Program Chairman, 824 S W Fifth Avenue, Portland 4, Ore

Pharmacologists Meet in Baltimore—The Abel Scientific meeting of the American Society for Pharmacology and Experimental Therapeutics will be held Sept 4 7 at the Johns Hopkins Medical Institutions, Baltimore Registration fee for the sessions is $5 00 A symposium on the teaching of pharmacology Sept 4 will be moderated by Alfred Gilman Presentation of papers will be followed by open discussions The Abel Centennial Symposium, in memory of John Jacob Abel, professor of pharmacology, Johns Hopkins Medical School, who died in 1932, will be presented Sept 5, and will include the following topics the chemistry of insulin, the significance of epinephrine in metabolism, the isolation of the hormones of the posterior pituitary, their chemical nature and some of their pharmacological properties The centennial dinner will be held the evening of Sept 5 For information write Harold C Hodge, Secretary, American Society for Pharmacology and Experimental Therapeutics, Inc, 260 Crittenden Boulevard, Rochester 20, N Y

Pathologists Meet in New Orleans—The annual joint meeting of the American Society of Clinical Pathologists and College of American Pathologists will be held in the Roosevelt Hotel, New Orleans, La, Sept 30-Oct 4 The following panel discussions are scheduled Preservations of Specimens for Future Investigation, with Dr Alan R Moritz, chairman, Mass Screening and the Pathologist Including "Package Deal," with Dr Albert E Casey, chairman, Philosophy and Conclusions of Workshop on Graduate Teaching of Pathology, with Dr Robert A Moore and Dr John R Schenken, co chairmen A symposium Oct 1 on clinical microbiology will be presented by Dr Lyle A Weed Workshops are scheduled for the afternoons of Oct 1 and 2 The 23rd annual seminar of the American Society of Clinical Pathologists is scheduled for Oct 4 A roundtable luncheon will be held Oct 2 The annual banquet will be held the evening of Oct 1 For information write Dr Arthur H Dearing, Executive Secretary, College of American Pathologists, Prudential Plaza, Chicago 1

Muscular Dystrophy Abstract Booklet—Muscular Dystrophy Associations of America, Inc, has announced a new service, the publication of a series of monthly muscular dystrophy abstracts for research scientists and others interested in muscular dystrophy and related diseases The project is being carried out with a subsidy from the association by the Excerpta Medica Foundation of New York and Amsterdam, Holland, for distribution throughout the world The first booklet presents summaries of 59 recent papers by scientists in this country and abroad The papers are classified into two groups abstracts from the clinician, concerned mainly with general anatomo-clinical publications, and abstracts of articles concerning the basic sciences relating to muscular dystrophy The abstracts are sent to association research grantees and clinic workers and other professional individuals and institutions The abstracts were published under the general editorship of the association's Medical Advisory Board For information write the Muscular Dystrophy Associations of America, Inc, 1790 Broadway, New York 19, N Y

Association of Medical Clinics Meeting—The eighth annual session of the American Association of Medical Clinics will be held at the Muehlebach Hotel, Kansas City, Mo, Oct 24-26 The presidential address will be given by Dr George McHardy, New Orleans Three panel discussions are scheduled Can Group Practice Reduce Incidence and Length of Hospitalization?, Areas of Responsibility of the Association, and Prepaid Medical Care with Special Reference to Ambulatory Patients Workshops, planned for Oct 25, will be moderated by Dr Frederick G Thompson Jr, St Joseph, Mo, Dr Olga Hansen, Minneapolis, Minn, Dr John R Hand, Portland, Ore, and Dr R Franklin Jukes, Akron, Ohio Luncheon guest speakers will be Dr William A Sawyer, medical consultant, International Association of Machinists, Rochester, N Y, and Major General Paul Robinson, executive director, Office for Dependents' Medical Care, Army Surgeon General's office, Washington, D C For information write the American Association of Medical Clinics, Dr Edwin P Jordan, Executive Director, Box 58, Charlottesville, Va

Science Research Grants—A total of $187,358 was awarded to 70 scientists in colleges and universities throughout the United States by Research Corporation during the second quarter of the year The corporation grants are aimed chiefly at initiating fundamental research in science where, because often new and sometimes bold ideas are involved, support is hard to get Research Corporation also announced that its Williams-Waterman Fund for the combat of dietary diseases has granted $109,242 to 26 scientists during the first six months of this year A nonprofit foundation, Research Corporation was established in 1912 by Frederick Gardner Cottrell with the gift of his patent rights in the field of electrical precipitation

The Williams-Waterman Fund was established in 1935 when Dr Robert R Williams and Robert E Waterman and their associates—the inventors of the processes for the synthesis of Vitamin B_1 and its intermediates—assigned their patents to Research Corporation The income from these patents is used to foster additional research both in the field of the physical sciences and in the specific area of nutrition

Study Program on Influenza—Arranged by the Pan American Sanitary Bureau, Washington, D C, a special team visited South America July 10-20 in connection with the World Health Organization study program on influenza The objective was to convey information regarding experience with the Far East Influenza epidemic, to advise on laboratory developments in connection with the virus, and to discuss types of information needed on the behavior of the disease under winter conditions, with ministers of health, directors of laboratories, and other medical authorities in Rio de Janeiro, Brazil, Buenos Aires and São Paulo, Argentina, and Santiago, Chile

The team comprised Captain John R Seal (MC), U S Navy, chairman, Advisory Committee for the World Health Organization Influenza Study Program in the United States, Dr Arturo C Saenz, of the Pan American Sanitary Bureau, Washington, D C, Dr William Jordan, Western Reserve University School of Medicine, Cleveland, and Dr Keith E Jensen, director, Influenza Strain Study Center for the Americas of the Communicable Diseases Center, Montgomery, Ala

Medical Writers Meet in St Louis—The 14th annual meeting of the American Medical Writers Association, will be held at the Sheraton-Jefferson Hotel, St Louis, Sept 27-28, under the presidency of Dr Dean F Smiley, Evanston, Ill, secretary, American Association of Medical Colleges Eighteen medical writers and authors will present papers A workshop on medical writing, conducted by full-time medical writers, will be held Sept 28, with speakers Drs Richard M *Hewitt, senior consultant, section on publications, and* George G Stilwell, medical editor, Mayo Clinic, Rochester, Minn Speakers for Sept 27 include the following Drs Russell L Cecil, New York City, James W Colbert Jr, St Louis, Morris Fishbein, Chicago, Jacques P Gray, Detroit, Joseph F Montague, New York, Robert W Schlesinger, St Louis, Austin Smith, Chicago, Sholom O Waife, Indianapolis, and John P Wyatt, St Louis Members of the association and other collegiate graduates are invited There is no charge for the meeting Sept 27, but there is a registration fee of $5 00 for nonmembers of the association who attend the workshop For information write Dr Harold Swanberg, Secretary, W C U Bldg, Quincy, Ill

Prevalence of Poliomyelitis—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated

Orthopedic Fellowships—Two fellowships have been awarded in the field of orthopedics by the National Foundation for Infantile Paralysis as part of its professional education program to Dr Charles E Workman, University of Kansas School of Medicine, Kansas City, and Dr David K Clawson, Stanford University School of Medicine, San Francisco Dr Workman was awarded a fellowship of $7,330, the second foundation fellowship to be granted to him to assist in his preparation for teaching and research in orthopedics His first fellowship, for 28 months, was for $11,200 He will study under the supervision of Dr Michael L Mason at Northwestern University, Chicago, and Dr Walter P Blount at Marquette University, Milwaukee He will also study scoliosis with Dr Joseph C Risser at the Clinic of Orthopedic Surgery in Pasadena, Calif On completion of the year's study, Dr Workman plans to return to the University of Kansas as a clinical instructor of orthopedic surgery

Dr Clawson is also receiving his second foundation fellowship designed to prepare him for orthopedic academic medicine and research His first fellowship, for $7,050 was for 24 months awarded in 1955 The second fellowship, for $7,190, is for 12 months, which he will spend at the Institute of Orthopaedics, Royal National Orthopaedic Hospital, University of London, under the supervision of H J Seddon, C M G, D M, director of studies

Annual Hospital Report—The ratio of hospital admissions to population in the continental United States outstepped the total population increase in the 11-year period 1946-1956, according to the annual report on hospital statistics published in *Hospitals*, Journal of the American Hospital Association Admissions to hospitals of all types in 1956 were 22,089,719 or 132 per thousand population In 1946 the rate was 112 per thousand population Over the 11-year period, the number of admissions climbed 41%, and from 1955 to 1956, nearly 5% The hospital statistics were compiled from questionnaires sent to 6,966 hospitals in the continental United States which had 1,607,692 beds and an average daily census of 1,355,792 in 1956 Of these hospitals, 51% were nonprofit, 17% proprietary, 6% federal, and 26% state and local governmental hospitals Although less than 2% of all admissions were to psychiatric hospitals in 1956, 53% of all patients in hospitals on any given day were in psychiatric institutions

The number of hospital births reported in 1956 was 3,491,141, an increase of 64% over 1946 but only 1% above the 1955 figure Length of stay in short-term general and special hospitals, which had dropped from 9 1 to 7 8 days from 1946 to 1955, went down 0 1 day to 7 7 days, and in proprietary hospitals 5 6 days, unchanged for these types from 1955 to 1956

Nonprofit short-term hospitals in 1956 spent $24 99 per day to care for each patient, an increase of 149% from the 1946 figure of $10 04 The rise from the 1955 level of $24 15 was a little over 3% From 1946 to 1956, the average cost to the hospital per patient stay rose from $88 35 to $187 43, an increase of 112% as compared with the 149% increase in the hospital's expense per patient day Full-time personnel employed by all hospitals totaled 1,374,704 in 1956, an increase of 66% in 11 years and nearly 6% in the last year of the period In all hospitals in 1956, there were an average of 101 personnel per 100 patients, an increase of 28 people per 100 patients in 11 years

FOREIGN

Congress of Military Medicine and Pharmacy—The 15th International Congress of Military Medicine and Pharmacy will be held Sept 29-Oct 5 in Belgrad, Yugoslavia Congress topics include the following medical services in armored and motorized operations, reduction of noise in the armed forces, radiation defense in military medicine, relations between the command of troops and medical services A special symposium on hypothermy will have the following topics physiology of hypothermy, application of hypothermy in clinics, and hypothermy and reanimation Speakers from New Zealand, France, Sweden, Argentina, Turkey, Great Britain, and the United States will make presentations Film programs concerning military medicine and health education are planned Entertainment includes visits to Kalemegdan Fortress and the Military Museum, a boat excursion on the rivers Sava and Danube, a banquet Aug 3, and a tour to Oplenac Resort A special ladies' program is scheduled For information write Col Dr Aleksandar Mezic, rue Nemanjina 15, Beograd, Yugoslavia

CORRECTIONS

Radioactive Isotopes in the Diagnosis and Treatment of Cancer—In the editorial by the foregoing title in THE JOURNAL, July 6, 1957, page 1097, righthand column, third paragraph, the symbol (S^{90}) should have been Sr^{90} In the same column, six lines from the bottom of the page, and in the two instances on the following page where the symbol (Cr^{51}) appears, the symbol (P^{32}) should be substituted for it

Frank Billings Lectureship—The proper title of the Frank Billings Lecture delivered by Dr E P Joslin in 1940 and listed in THE JOURNAL, July 27, 1957, page 1485, was "Universality of Diabetes Survey of Diabetic Morbidity in Arizona"

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS *Part I* Various Centers, Sept 3-4 Sec, Dr John B Hubbard 133 South 36th St Philadelphia 4

MEDICAL SPECIALTY BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY *Oral* Washington Oct 28-Nov 1 Various locations in the United States and Canada, July 18 Final date for filing application is Jan 18 Sec, Dr Curtiss B Hickcox, 80 Seymour St, Hartford 15

AMERICAN BOARD OF DERMATOLOGY *Oral* Baltimore, Oct 11-13 Final date for filing application was April 1 Sec, Dr Beatrice Maher Kesten, One Haven Ave, New York 32

AMERICAN BOARD OF INTERNAL MEDICINE *Written* Oct 21 *Oral* Los Angeles, Sept 11-14 Final date for filing applications was Feb 1 Exec Sec, Dr W A Werrell, 1 West Main St, Madison 3, Wis

AMERICAN BOARD OF NEUROLOGICAL SURGERY Examination given twice annually, in the spring and fall In order to be eligible a candidate must have his application filed at least six months before the examination time Sec, Dr Leonard T Furlow, Washington University School of Medicine, St Louis 10

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY *Part I* Chicago Jan 2 *Part II* Chicago, May 7-17 Final date for filing application is September 1 Sec, Dr Robert L Faulkner, 2105 Adelbert Road, Cleveland 6

AMERICAN BOARD OF OPHTHALMOLOGY *Oral* Chicago Oct 7-11 *Written* January 1958 Final date for filing application was July 1 Sec, Dr Merrill J King, Box 236, Cape Cottage Branch, Portland 9 Maine

AMERICAN BOARD OF ORTHOPAEDIC SURGERY Parts I and II, New York City, Jan 29-31, 1958 Final date for filing application is August 15 Sec, Dr Sam W Banks 116 South Michigan Avenue, Chicago 3

AMERICAN BOARD OF OTOLARNGOLOGY Chicago Oct 7-11 Final date for filing application was in April Sec, Dr Dean M Lierle, University Hospitals, Iowa City

AMERICAN BOARD OF PATHOLOGY *Oral and Written Pathologic Anatomy and Clinical Pathology* New Orleans, Sept 26-28 Final date for filing application is August 15 Sec, Dr Edward B Smith, Indiana University Medical Center, Indianapolis 7

AMERICAN BOARD OF PEDIATRICS *Oral* Chicago Oct 11-13 Sec, Dr John McK Mitchell, 6 Cushman Road, Rosemont, Pa

AMERICAN BOARD OF PLASTIC SURGERY *Oral and Written Examination* San Francisco Oct 31-Nov 2 Final date for filing case reports was July 1 Corresponding Sec Miss Estelle E Hillerich 4647 Pershing Ave, St Louis 8

AMERICAN BOARD OF PREVENTIVE MEDICINE *In Public Health Oral and Written* Cleveland, Nov 7-9 Sec, Dr Thomas F Whayne, 3438 Walnut St, Philadelphia

AMERICAN BOARD OF PROCTOLOGY *Oral and Written Parts I and II* September Sec, Dr Stuart T Ross, 520 Franklin Ave, Garden City, N Y

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY New York Dec 16-17 San Francisco, March 17-18 Sec, Dr David A Boyd, Jr, 102-110 Second Ave, S W, Rochester, Minn

AMERICAN BOARD OF RADIOLOGY Washington, Sept 23-28 Final date for filing application was June 1 Chicago May 20-24 Final date for filing application is Jan 1 1958 Sec, Dr H Dabney Kerr Kahler Hotel Bldg, Rochester, Minn

AMERICAN BOARD OF SURGERY *Part II* Buffalo Sept 23-24 New Haven, Oct 21-23 Indianapolis, Nov 18-19, Cincinnati, Dec 16-17 New Orleans Jan 13-14 Durham, N Car, Feb 10-11, Baltimore, March 10-11, Chicago, May 12-13, Los Angeles, June 16-17 and Portland, Oregon June 20-21 Sec, Dr John B Flick, 225 So 15th St, Philadelphia 2

AMERICAN BOARD OF UROLOGY *Written examination* Various cities throughout the country *Pathology and Oral Clinical* February 1958 Location not decided Exec Secretary, Mrs Ruby L Griggs, 30 Westwood Road, Minneapolis 16

BOARD OF THORACIC SURGERY *Written* Various centers throughout the country, Sept 6, and the closing date for registration was July 1, 1957 Sec, Dr William H Tuttle, 1151 Taylor Ave Detroit 2

GOVERNMENT SERVICES

Ide, Clarence Edward, San Diego, Calif, Columbia University College of Physicians and Surgeons, New York City, 1894, veteran of World War I, died May 26, aged 87, of arteriosclerotic heart disease

Jonitz Robert ⊕ Greenville, S C, McGill University Faculty of Medicine, Montreal, Quebec, Canada, 1930, on the staffs of the St Francis and Greenville General hospitals, certified by the National Board of Medical Examiners, died June 10, aged 56, of congestive heart failure

Kaufman, Irving ⊕ Boston, College of Physicians and Surgeons, Boston, 1941, associated with the Massachusetts Memorial Hospitals, where he died June 11, aged 48, of uremia

Kavanagh, Joseph James, San Francisco, University of California School of Medicine, San Francisco, 1903, veteran of World War I, died in Yountville June 10, aged 75

Kemp, Richard Joseph, Washington, D C, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1921, member of the Medical Society of the District of Columbia, veteran of World War I, member of the staffs of the Children's Hospital and the Episcopal Eye, Ear, and Throat Hospital, honorary police inspector, died in the National Institutes of Health, Bethesda, Md, May 2, aged 62, of cancer

Kempf, Raymond Aloysius, Utica, N Y, University and Bellevue Hospital Medical College, New York City, 1910, an honorary member of the staff of St Elizabeth Hospital, died May 20, aged 69

Kerr, Joseph T ⊕ Wilson, N C, Jefferson Medical College of Philadelphia, 1935, fellow of the American College of Surgeons, member of the staff of the Carolina General Hospital, died in Wilmington June 17, aged 50

Kesmodel, Karl Frederick ⊕ Birmingham, Ala, Tulane University School of Medicine, New Orleans, 1916, specialist certified by the American Board of Radiology, member of the Radiological Society of North America and the American College of Radiology, past-president of the Jefferson County Medical Society, for many years served in the regular U S Army, veteran of World War I, died in St Vincent s Hospital May 27, aged 63, of septicemia and pyelonephritis

Klaus, Henry, Union City, N J, Columbia University College of Physicians and Surgeons, New York City, 1912, fellow of the American College of Surgeons, veteran of World War I, on the staff of the Christ Hospital in Jersey City, died June 4, aged 68, of coronary thrombosis

Kloman, Erasmus H, Baltimore, University of Maryland School of Medicine, Baltimore, 1910, also a graduate in pharmacy, member of the Medical and Chirurgical Faculty of Maryland, past-president of the Board of Medical Examiners of Maryland, fellow of the American College of Surgeons, at one time on the faculty of his alma mater, veteran of World War I, associated with the Maryland General Hospital, died April 30, aged 72

Kramer, Floyd, Colonel, U S Army, Pelham, N Y, Starling-Ohio Medical College, Columbus, 1908, service member of the American Medical Association, entered the medical corps of the U S Army in 1910, rose through the various grades to that of colonel on May 28, 1936, retired Jan 31, 1942, died in Lawrence Hospital, Bronxville, June 16, aged 73, of cerebral hemorrhage

Krenz, Carl ⊕ Long Island City, N Y, Yale University School of Medicine, New Haven, Conn, 1925, medical examiner for the Selective Service during World War II, at one time instructor in pathology at Western Reserve University School of Medicine in Cleveland, on the staffs of the Physicians Hospital in Jackson Heights and the Queens General Hospital in Jamaica, died June 14, aged 56, of coronary disease

Kulp, Raymond Ranney ⊕ Bettendorf, Iowa, State University of Iowa College of Medicine, Iowa City, 1904, served overseas during World War I, on the staffs of the St Luke's and Mercy hospitals in Davenport, died May 21, aged 78, of coronary occlusion

Laird, Everitt Holmes ⊕ Aliquippa, Pa, University of Pittsburgh School of Medicine, 1928, member of the American Academy of General Practice, died March 8, aged 58

Lamy, Rudolf ⊕ Franklin Square, N Y, Schlesische Friedrich-Wilhelms-Universitat Medizinische Fakultat, Breslau, Prussia, Germany, 1922, member of the American Academy of General Practice, died May 20, aged 62

Langheim, Henry William, Napa, Calif, the Hahnemann Medical College and Hospital, Chicago, 1899, at one time associated with the Indian Service in Lawton, Okla, died in the Parks Victory Memorial Hospital April 26, aged 86

Lawwill, Robert Lewis ⊕ West Union, Ohio, Eclectic Medical College, Cincinnati, 1922, served as health commissioner of the Adams-Brown counties health district, administrator of the Adams County Hospital, where he died April 20, aged 60, of coronary thrombosis

Le Merle, Eugene Lyman, Washington, D C , Columbian University Medical Department, Washington, 1897, served as chief of contagious diseases of the District Health Department, on the staff of the Central Dispensary and Emergency Hospital, died in Ashton, Md June 13, aged 86, of bronchopneumonia

Leonard, Marion Brady, New Haven, Conn , Yale University School of Medicine, New Haven, 1931, member of the Connecticut State Medical Society, died Jan 9, aged 52, of cerebral hemorrhage

Lepke, Joseph Elmer ⊕ Chicago, Rush Medical College, Chicago, 1923, died in the Jackson Park Hospital June 6, aged 59, of arteriosclerotic heart disease

Lester, John Elbert ⊕ Marietta, Ga , Atlanta College of Physicians and Surgeons, 1902, for many years county health commissioner, died May 11, aged 80, of a cardiovascular accident

Levy, Abraham Nathan ⊕ New York City, University and Bellevue Hospital Medical College, New York City, 1912, died in the Queens General Hospital, Jamaica, June 10, aged 68

Lewis, Henry L ⊕ Liberty, Miss , Louisville (Ky) Medical College, 1892, on the staff of the Field Memorial Hospital in Centreville, died May 17, aged 89, of bronchopneumonia

Longabaugh, Rudolph Ignatius, Captain, U S Navy, retired, San Mateo, Calif , University of California School of Medicine, San Francisco, 1903, fellow of the American College of Surgeons, service member of the American Medical Association, veteran of World Wars I and II, entered the U S Navy in 1907 and retired April 11, 1925, in 1940 recalled to active duty, again retired in 1946, died May 16, aged 75

Long, Walter Richard ⊕ Philadelphia, Temple University School of Medicine, Philadelphia, 1933, veteran of World War II, associated with Nazareth Hospital, St Mary's Hospital, and Eugenia Memorial Hospital, where he died June 10, aged 53, of acute myocardial infarction

Lyons, Joseph William ⊕ Stollings, W Va , University of Pennsylvania School of Medicine, Philadelphia, 1909, veteran of World War I, president and part owner of the Holden (W Va) Hospital, died in St Marys Hospital, Huntington, May 29, aged 73, of liposarcoma

McAdow, Ernest B , De Kalb, Mo , Ensworth Medical College, St Joseph, Mo , 1897, Lincoln (Neb) Medical College of Cotner University, 1896, died June 14, aged 84

McCarty, Paul Dean ⊕ Tower, Minn , Rush Medical College, Chicago, 1906, died April 24, aged 73, of acute coronary thrombosis

McGinnis, Daniel H , Detroit, University of Western Ontario Faculty of Medicine, London, Ontario, Canada, 1922, died in the Henry Ford Hospital April 6, aged 62, of adenocarcinoma of the colon

Magune, Frank Leroy ⊕ Worcester, Mass , Medical School of Maine, Portland, 1904, fellow of the American College of Surgeons, for many years physician at the Worcester County Jail, served on the staff of the Worcester City Hospital, died May 11, aged 76, of carcinoma of the prostate

Malik, Edward Anthony ⊕ Detroit, Wayne University College of Medicine, Detroit, 1939, interned at the Grace Hospital, died June 1, aged 49

Marshall, Roy Jay ⊕ Rome, N Y , Albany (N Y) Medical College, 1910, veteran of World War I, formerly city health officer, on the staff of the Rome Hospital and Murphy Memorial Hospital, where he died June 12, aged 70, of cerebral hemorrhage

Mackenzie, Donald William, Indianapolis, University of Louisville (Ky) Medical Department, 1894, veteran of World War I and the Spanish-American War, died in Martinsville May 6, aged 88, of myocardial failure

Marcy, William Henry, Buffalo, New York Homeopathic Medical College and Hospital, New York City, 1893, fellow of the American College of Surgeons, an associate member of the American Medical Association, served as president of the Association of New York Central Lines Surgeons, consultant, Millard Fillmore Hospital, died in Gulfport, Fla , May 18, aged 86

Marxuach, Manuel Jose, New York City, University of Virginia Department of Medicine, Charlottesville, 1899, died in St Vincent's Hospital April 3, aged 82, of arteriosclerosis

Mason, John Franklin, Bradenton, Fla , Southern College of Medicine and Surgery, Atlanta, 1912, an associate member of the American Medical Association, died May 22, aged 69, of a heart attack

Matus, Morris Rudolph, Bayside, N Y , University and Bellevue Hospital Medical College, New York City, 1922, for many years member of the New York City Health Department, clinical instructor at the New York Medical College, Flower and Fifth Avenue Hospitals, associated with the Queens General Hospital in Jamaica, died May 30, aged 56, of coronary thrombosis

Maynard, Donald Edmund ⊕ Glenview, Ill , Northwestern University Medical School, Chicago, 1922, died June 17, aged 62, of coronary occlusion

Meyer, Alfred Henry, Camdenton, Mo , St Louis College of Physicians and Surgeons, 1906, died May 2, aged 75

Miller, Edgar T., Woodbury, Conn , University of Pennsylvania Department of Medicine, Philadelphia, 1894, served on the staff of the Bryn Mawr (Pa) Hospital, died May 10, aged 88, of arteriosclerosis and prostatic hypertrophy with uremia

Morrow, James S, St Joseph, Mo , Ensworth Medical College, St Joseph, 1908, died in the Missouri Methodist Hospital May 21 aged 83 of cerebral hemorrhage

Morrow, Samuel Jerome ⊕ Inman, S C , Medical College of South Carolina Charleston, 1927, for many years served as surgeon for the Southern Railway, on the staff of the Spartanburg (S C) General Hospital charter member of the Inman Rotary Club, died May 7, aged 56 of coronary thrombosis

Nolte, Willis Clever, Nampa, Idaho, Northwestern University Medical School, Chicago, 1904, an associate member of the American Medical Association, died in Boise March 20, aged 77, of multiple myeloma

Norris, Maurice N ⊕ Los Angeles, University of Minnesota Medical School Minneapolis, 1922, died April 13, aged 61

Nuzzo, William Benjamin ⊕ Albany, N Y , Tufts College Medical School, Boston, 1931, veteran of World War II, member of the staffs of the Veterans Administration and Child's hospitals, died May 26, aged 50

Old, Herbert, Philadelphia, University of Virginia Department of Medicine, Charlottesville, 1895, an associate member of the American Medical Association, retired medical director of the Provident Mutual Life Insurance Company, died May 24, aged 85, of coronary thrombosis

Onorato, Victor Anthony, Buffalo, Fordham University School of Medicine, New York City, 1919, died in the Sisters Hospital May 26, aged 62

Peus, Carl Joseph, San Fernando, Calif , Universitat Leipzig Medizinische Fakultat, Saxony, Germany, 1925, associated with the Veterans Administration Hospital, where he was chief of the radiology division, service member of the American Medical Association died April 6, aged 57

Prince, Frank Joseph, Stevensville, Mont , Medical College of Ohio, Cincinnati, 1907, died May 21, aged 84, of cerebral hemorrhage

Ray, James Taylor, San Francisco, College of Physicians and Surgeons of San Francisco, 1910, served on the staffs of St Luke's and Franklin hospitals, died in Happy Camp, May 21, aged 70, of myocardial infarction

Reidel, Christian Francis ⊕ Syracuse, N Y , Syracuse University College of Medicine, 1914, served on the staff of St Joseph's Hospital, died May 18, aged 68, of acute coronary occlusion

Roberts, Francis LeRoy ⊕ Corona, Calif , State University of Iowa College of Medicine, Iowa City, 1935, member of the Iowa State Medical Society, formerly practiced in Spirit Lake, Iowa, died May 20, aged 63

Rolph, William Donald ⊕ National City, Calif , Cornell University Medical College, New York City, 1914, veteran of World War I, past-president and a charter member of the National City Kiwanis Club, died in Scripps Memorial Hospital, La Jolla, May 25, aged 68

Root, Charles Theodore ⊕ Jacksonville, Ill , University of Michigan Homeopathic Medical School, Ann Arbor, 1914, member of the American Society of Anesthesiologists and the American Trudeau Society, veteran of World War II, died in the Veterans Administration Hospital, Ann Arbor Mich , April 10, aged 74, of myocardial infarct and coronary arteriosclerosis

Rosenberg, David, Oakland, N J , University and Bellevue Hospital Medical College, New York City, 1934, service member of the American Medical Association, formerly associated with the Veterans Administration, died April 28 aged 60, of coronary heart disease

Selby, Paul Norman, Boston, Tufts College Medical School, Boston, 1956, intern, Beth Israel Hospital, was killed in an automobile accident May 23, aged 25

Selman, Ralph Jackson, Ottumwa, Iowa, Keokuk (Ia) Medical College, College of Physicians and Surgeons, 1908, an associate member of the American Medical Association, member of the American Academy of General Practice, veteran of World Wars I and II, associated with Ottumwa Hospital and St Joseph Hospital, where he died April 26, aged 70, of acute coronary occlusion

Smith, William Alexander, Boyd, Wis , Trinity Medical College, Toronto, Ontario, Canada, 1902, served on the staffs of the St Joseph's Hospital, Chippewa Falls, and Sacred Heart Hospital, Eau Claire, died in the Luther Hospital, Eau Claire, April 25, aged 78, of heart disease

Street, John Paul, Minneapolis, University of Minnesota Medical School, Minneapolis, 1951, served on the faculty of his alma mater, member of the staff of the Veterans Administration Hospital, where he died April 28, aged 31, of subarachnoid hemorrhage

Turner, Dan Bonelle, San Antonio, Texas, Louisiana State University School of Medicine, New Orleans, 1945, member of the Industrial Medical Association, served as a major in the medical corps of the U S Air Force Reserve, died in the Brooke Army Hospital, Fort Sam Houston May 8, aged 35, of uremia and chronic bilateral glomerulonephritis

Volkhardt, Vida Redington, Palo Alto, Calif , University of California School of Medicine, San Francisco, 1899, died March 21, aged 82, of cerebral hemorrhage

White, Robert Frank, Pine Bluff, Ark , University of Nashville (Tenn) Medical Department, 1901, for many years surgeon for the Missouri Pacific Railroad while at Mc Gehee, died in the Davis Hospital May 20, aged 83, of cerebral thrombosis and cerebral arteriosclerosis

Williams, J Odell ⊕ Emporia, Kan , University Medical College of Kansas City, Mo , 1905, veteran of World War I, died May 7, aged 77

Willis, Raymond Shelfer ⊕ Dallas, Texas, Baylor University College of Medicine, Dallas, 1933, veteran of World War II, one of the founders of the East Dallas Hospital and Clinic, died April 27, aged 53

FOREIGN LETTERS

ARGENTINA

Argentine Pharmacopeia —Before 1898 the French Codex Medicamentarius was used as a pharmacopeia in Argentina, but in 1893 an Argentine Pharmacopeia was established by law The first edition was published in 1898, the second in 1921, the third in 1941, and the fourth in 1955 The pharmacopeias of various countries are gradually approaching a standard The last two editions of the Argentine Pharmacopeia have shown an increasing similarity to that of the United States

Hypoglycemic Sulfonamides —The Argentine Society of Diabetes sponsored a symposium on the pharmacological action of carbutamide and tolbutamide A study of more than 700 cases showed that both substances have a similar effect, but tolbutamide is better tolerated No deaths have been attributed to these drugs Good results were obtained in 70 to 80% of the obese diabetic patients over 40 years of age, many of whom did not require insulin On the other hand, results were almost always poor in patients with infantile or juvenile diabetes or in those with labile forms requiring insulin who fall into coma or acidosis when insulin is not given

Charity Hospitals —In 1922 the government, under the presidency of Bernardino Rivadavia, placed in the hands of a committee of women the task of organizing a charity society in Buenos Aires with the purpose of founding hospitals and asylums for the assistance of women and children who were sick and also indigent Later, similar societies appeared in other provinces The Peron government dissolved these societies, and all their properties were turned over to the Eva Peron Foundation They are now in the charge of the Ministry of Public Health and Welfare

Quackery —Miraculous properties are being attributed to various new products The bee royal jelly is being widely sold at a high price as a marvellous panacea, and some newspapers have printed sensational reports on the cure of cancer by prednisolone and other products Much less dangerous are the activities of some physicians who claim they can cure many diseases by acupuncture and make diagnoses by examination of the iris

AUSTRIA

Water and Electrolyte Excretion —At the meeting of the Vienna Society for Pediatrics in June, H Frischauf and E Zweymuller reported on the results of examinations in 10 children with exogenous obesity who showed an increased excretion of metabolic water, sodium, and chloride, whereas potassium was retained The bound water level remained unchanged The renal excretion of sodium was almost independent of the renal excretion of water An increased excretion of water took place through an increase of the insensible perspiration The nitrogen balance, negative at the beginning, was adjusted in the course of 10 to 14 days

Hyaline Membranes in the Lungs —At the same meeting, A Mann reported on 23 cases of hyaline membranes in the lungs of newborn infants This series represented 18 5% of the premature infants who died at the Vienna Pediatric Clinic in the years 1955 and 1956 The characteristic pathological triad consisted of extensive atelectasis, capillary hyperemia, and hyaline membranes, which appeared, when stained with eosin, as shining red bands attached to the alveolar walls and passages The course of the disease is marked by a "calm interval" in the first hours of life in which these babies are not distinguished from the normal ones Roentgenograms show that the disease begins with small spots on the lungs and progresses to the collapse of a single lobe or of a whole lung

Reestablishment of Intestinal Flora —At the same meeting, E Huber said he had treated 89 children, of whom 63 were nursing infants, for two and one-half years with Mutaflor (coliform bacteria preparation) This preparation contains an emulsion of living Escherichia coli and is given after antibiotics have destroyed the normal intestinal flora and after acute or chronic enteritis It cannot be given to unconscious children, patients with ileus, or patients with enteritis in the acute stage The results of the treatment were clinically and bacteriologically good

Prostatic Resection —At the meeting of the Austrian Society for Urology in June, Salomon reported on the resection of the prostate of 82 patients with the use of a combined spark spacer and tube current apparatus When this technique is used, indications can be broadened to include patients in poor general condition and those with poor renal function A follow-up of 62 patients revealed that 43 were free from residual urine, 18 had 50 cc, and 1 had 200 cc of residual urine and urinary infection and dysuria The combination of optimal cutting and coagulation current permitted a faster resection than was possible with other techniques The mortality was slightly over 1%

Partial Nephrectomy —At the same meeting, Bibus said that the best technique for partial nephrectomy consists of a frontal wedge-shaped resection, compression of the renal pelvis by hand, free ligation of the bleeding vessels, and the closure of the renal parenchyma by deep parenchymal sutures and delicate suturing of the capsules A drainage tube into the renal cavities is introduced only if needed The mucosa of the renal pelvis is sutured when closed without drainage Renal calculus was the most frequent cause for operation Partial nephrectomy was performed less frequently in patients with hydronephrosis and rarely

The items in these letters are contributed by regular correspondents in the various foreign countries

in those with tuberculosis. The speaker believed that nephrectomy is performed too often in patients with renal tuberculosis.

Agranulocytosis After Treatment with Ethyleneimine Quinone.—At the meeting of the Vienna Society of Physicians on June 28, I. Schwert and R. P. Konigstein reported the case of a 59-year-old woman with inoperable carcinoma of the ovary with metastases to the omentum and ascites. Ethyleneimine quinone (E-39) was given intraperitoneally, intravenously, and orally after a temporary improvement following treatment with radium and roentgen irradiation. The ascites disappeared and the subjective complaints improved. A decrease of leukocytes from 3,300 to 1,050 within 24 hours was seen after a total dose of 610 mg. of the drug had been given. The drug therapy was discontinued, but the leukocyte count decreased to 400 within the next week and a high fever developed. Neither granulocytes nor juvenile cells could be detected by sternal puncture or in the peripheral blood. Full hematological and clinical recovery followed treatment with antibiotics and prednisolone. Treatment with E-39 was resumed and the patient was concurrently given prednisolone. No further decrease of leukocytes occurred.

Ultrasound Pictures.—At the same meeting, G. Keck stated that roentgenograms can be made by means of an ultrasonic lens. Such a roentgenogram is best obtained by a sound lens with an ultrasonic wave length of 0.38 mm. and a resolving power of 2 mm. in water and with a wave length of 0.23 mm. and a resolving power of 1.2 mm. when not in water. Whether useful pictures of the inner parts of the body can thus be obtained or not depends essentially on the behavior of the ultrasound with regard to absorption, deviation, reflection, and total reflection on the object.

Meningitis.—At the same meeting, E. Wodak stated that all patients with otogenous, rhinogenous, and post-traumatic focal meningitides should be operated on. In addition to the operation and by means of both spinal and suboccipital punctures in patients with severe disease, the speaker irrigates the sac of the cerebrospinal fluid with physiological sodium chloride solution. From 10 to 20 cc. of air and aqueous penicillin are injected intrathecally. At the first sign of improvement this therapy is discontinued. The speaker cautioned against the use of antibiotics without supervision by the otorhinologist. Especially when there is a suggestion of otogenous or rhinogenous complication, antibiotics should be given only after the condition has been thoroughly studied.

Cooperation Between University and Public Health Service.—At the second International Congress for Social Medicine, held in Vienna May 30 to June 2, P. Bonnevie of Copenhagen said that the medical school has the double task of training prospective physicians and promoting medical science. Governmental health activities are increasing throughout the whole world, due to the concept of social responsibility for public health. In listing health-promoting factors, the speaker included individual, social, private, and public measures for prophylaxis and general welfare, physical, mental, and cultural adjustment, education, and rehabilitation. Unfortunately, it is more difficult to elicit financial support for activities pertaining to sanitation than for a fight against a specific type of germ or disease. An important measure in every program of sanitation consists in directing the medical profession toward health and not toward illness. This can be accomplished through medical education, but its success depends on whether those responsible for such direction are active in practical health work. The instruction should not be merely theoretical but should be based on the instructor's concrete experiences. Education in public health is part of general medical education and is mostly limited to courses of short duration. Students who wish to become health officers should have the opportunity of taking a comprehensive postgraduate course. In some countries the ministry of public health takes care of this education, in other countries special schools do this.

Such a distinction of the postgraduate courses for physicians in public health has its risks, since the subjects taught might be considered as lying outside of the usual medical education program. The teaching of public health should be integrated with the rest of the medical course. This has been the case in Denmark for 50 years. The university institute for hygiene in Copenhagen developed its program from physiology, not from pathology. From the beginning, such subjects as nutrition, conditions of work and housing and school hygiene have been stressed. The director has always been a person who was both a professor in the university and a member of the board of health. Several laboratories of the public health service such as the National Laboratory for Vitamins and the National Institute for Occupational Hygiene are lodged in the university. Furthermore, the directors of the university departments of veterinary medicine and other technical departments are members of the board of health. In the course of time, the hygienic education of medical students has been extended. Social insurance is taught within the branch of legal medicine, epidemiology is taught with microbiology, prophylaxis is a part of all clinical courses, eugenics is part of human genetics, and dietetics is often combined with biochemistry. Introductory lectures on medical statistics are given in the first year of medical study. Thus an attempt has been made to make hygienic problems part of every medical specialty and to give the Danish physicians a broad concept of them so that the postgraduate courses in public health could be condensed to a length of only four months. In Denmark the number of health officers is limited as much as possible, to let all the general practitioners cooperate in the prophylactic and sociomedical work.

New Order in the European Faculties of Medicine.—At the same meeting, Prof. Dr. J. Stuchlik of Prague said that it was impossible to discuss thoroughly the influence of the political attitudes and policies on European universities. Even a science supposedly as "unpolitical" as medicine is no exception. The main purposes of a faculty of medicine are education and research. Changes in the pattern of research in recent years include the fact that much medical research is now being conducted, not by universities but, by industries. This is especially true in chemistry and pharmacology. Furthermore, much research in biology and physiology is now done in nonuniversity hospitals. With regard to teaching in some countries, there are no longer any faculties of the whole of medicine, but there are special professional schools with different limits which still might be called faculties in some places. For example, there are faculties of therapeutics, pediatrics, and preventive medicine that are independent of each other, having their own curriculum and a duly limited field of activity of their fellows. In other countries, postgraduate education is carried on in institutions separated from the university. The role of the undergraduate school thus loses importance. The formal part of education in the specialties and the conferring of degrees has been taken from the university faculties and given to academies and ministries. The basic sciences and philosophy are neglected intentionally in some places, or they are taught more or less dogmatically.

Teaching Hygiene and Preventive Medicine in Finland.—At the same meeting, Prof. Dr. W. Lojander of Helsinki said that, although clinical medicine is still more attractive to most students, interest in preventive medicine is increasing. Incomes of physicians in this field are much lower than those of clinicians, but steps are being taken to improve the pay of health officers. In the last decade the medical school of the University of Helsinki has added courses in social medicine and public health. In recent years, between 100 and 120 students, yearly, have taken the special course in public health. Owing to the increasing importance of social medicine and the Finnish regulations on the medical profession which oblige the district physician not only to care for the sick but to protect the health of the well, there is a growing interest in preventive medicine. The public is beginning to realize what some physicians have long understood—that a nation's most important capital is neither gold nor goods but health and productive power. The people with the most and the best hospitals are not as healthy as the people who have the least need of them.

BRAZIL

Alterations of Mycobacterium Tuberculosis.—Brandi and Lopes reported to the Associacão Paulista de Medicina on a study of 114 strains of Mycobacterium tuberculosis isolated from 61 patients treated with various tuberculostatic drugs in about a year in a sanatorium. The number of strains resistant to one or more units of isoniazid was about twice that of sensitive strains. The number of strains of standard virulence but showing resistance (30.7%) was lower than the number of sensitive strains of identical virulence (52.7%). This loss of virulence was directly proportional to the increase in resistance, but an important fact was the entire absence of standard virulence in all R-100 strains. Some avirulent strains or strains of low virulence showed an appreciable sensitivity even to total dosages as low as 72 Gm. of isoniazid, but this phenomenon was not observed in relation to streptomycin. The study of the relationship between the amount of the drug given, the titer of the sensitivity to isoniazid, and the virulence to guinea pigs showed that up to 13 Gm. there was a predominance of sensitive strains of standard virulence. Increasing amounts of the drug gradually produced a reversal of that tendency, causing the appearance of larger numbers of sensitive strains of low virulence. Nevertheless, sensitive strains may persist even with large amounts of the drug. The negative activity in the presence of catalase was the only test that showed a relationship with the resistance to isoniazid, a clear relationship being observed with the virulence to guinea pigs only with the strains of very low virulence, since the number of catalase-negative cases was significantly larger than that of catalase-positive ones. The study of the general evolution of the tests of sensitivity to the drugs, of the virulence to guinea pigs, and of activity in the presence of catalase of the bacilli isolated from the same patients showed a certain margin of disagreement between the several tests, making it impossible to establish an exact relationship between the tests.

Otitis and Mastoiditis.—Marone and Calabria (*Rev. Hosp. clín.* 12:145, 1957) studied 172 patients with otitis and mastoiditis; 22 had acute suppurative otomastoiditis, 75 had simple chronic otomastoiditis, and 75 had chronic cholesteatomatous otomastoiditis. Because of the importance of its pathology and its complications, the authors gave the age distribution of the patients with cholesteatomatous otomastoiditis: 15 patients were infants to 2 years old, 10 were 3 to 6, 14 were 7 to 13, 16 were 14 or over, and in 20 the age was not recorded. Among those with acute otomastoiditis there were two cases of meningitis, and two of facial paralysis. In one child of 12 years a retroauricular abscess developed. This patient was first treated with small doses of sulfanilamide and later subjected to radical mastoidectomy; a subdural abscess formed and the child died. Of the 75 patients with simple chronic otomastoiditis, there was a case of meningitis and a case with fatal termination not well explained. Among the 75 cases with cholesteatomatous otomastoiditis, there were three cases of meningitis, two of cerebral abscess, two of encephalitis, and one of facial paralysis due to cerebral abscess. Two patients in this group died. With the improvement of the therapeutic methods there was a sharp decline in complications in recent years. No patients with the acute form of the disease were seen after 1954, and the incidence of the other two forms has shown a steady decline.

Lithiasis and Stenosis of the Common Bile Duct.—Dr. Alfredo Wazen (*Rev. brasil. cir.* 33:251, 1957) reported a series of 23 selected cases of lithiasis of the ductus choledochus, some simple and some associated with stones in the gallbladder. Among the latter, nine were residual, including six cases in which the diagnosis was made by means of postoperative cholangiography. Pribam's method was used five times with one failure, which necessitated a second operation. Six patients had stenosis of the duct, and three of them developed the condition after operative trauma Among the operations performed, there were one resection and terminoterminal anastomosis of the ductus choledochus (with excellent result), one hepatoenterostomy (with good result), and two attempts at fistulo-anastomosis (one patient died and one had a poor result) Of two patients with stenosis of Oddi's sphincter, one had pancreatitis which was cured and the other, in whom the radiologic findings continued the same without any subjective complaint or objective manifestation for four months, was still under observation and apparently well The author stressed the diagnostic value of roentgenography in the absence of jaundice Choledochotomy is mandatory when the common bile duct is found dilated and thick, the cystic duct is dilated, stones are felt, and the gallbladder is scleroatrophic The author closes the choledochotomy about a T-tube which is used for the postoperative cholangiography and is left occluded for two or three days to observe the occurrence of pain, a phenomenon which indicates that the tube should not be removed

Due to antibiotics, duodenotomy does not increase the operative risk The author performed this operation six times without accidents Strictures of the common bile duct are a matter of serious concern The congenital ones, when not treated by surgery, do not permit a survival over seven months Operative injury causes most of such strictures and is easily overlooked It is important to identify the cystic artery and the cystic duct before ligation The best treatment is end-to-end anastomosis using nonabsorbable sutures on a branch of a Kehr s tube, which is not removed before six months In certain cases, a palliative short-circuit is mandatory choledochoduodenostomy and choledochojejunostomy Anastomosis of the hepatic parenchyma and the jejunum was performed in one patient with common duct strictures in whom end-to-end anastomosis was not feasible The patient was living and well when last seen Grafts are not dependable and should be abandoned

CANADA

C M A General Council Meets—The General Council and Executive Committee of the Canadian Medical Association has created a department of medical economics or economic research at C M A headquarters The original idea was to have this department headed by a physician, but it may be necessary to recruit a lay economist for the job The department will have the task of collecting data from provincial medically sponsored health insurance plans, analyzing and evaluating the data, and making the results available to the profession It is intended that this department shall be of practical value and not concerned with academic problems Much useful statistical material is buried at the provincial level A study will also be made of the principles of job evaluation as they apply to the economics of the Canadian medical profession This is obviously a long-term study, and the first part will attempt 'to set up a listing of medical procedures so that the relative value of each will reflect the difference in degree of the medical responsibilities involved " This will require much work at the national and provincial levels and will call for the collaboration of the new department of economic research

One resolution of council was probably inspired by the plight into which the British Medical Association has gotten with its government Mindful that their British colleagues have no effective medium for arbitration in the National Health Service, the council added to its statement of principles respecting health insurance the following principle "No doctor or group of doctors should enter into an agreement respecting remuneration for professional services with any governmental semi-governmental, or non-governmental body, without prior assurance of a recognized system for the arbitration and negotiation of issues such as remuneration and terms of service " The likelihood that a national hospital insurance scheme is just around the corner led to two other positive steps First, a strong advisory committee to the federal government was appointed with the understanding that this committee was to be the sole negotiating body and spokesman for the C M A with the federal government or its departments It is hoped that with the cooperation of L'Association des Medecins de Langue Française, representing most of the French-speaking physicians of Canada, a united front can be presented to the government in contrast to the disastrous situation in England where more than one body has claimed the privilege of negotiating for parts of the profession Second, there was much debate on the possibility of preparing a plan for comprehensive hospital services, diagnostic services, and physicians' services based on the principles of prepaid insurance approved by the association, presumably as a counterblast to any plan that might be evolved by government advisers outside the profession It was finally agreed that a committee should review the statement of principles in order to indicate methods of implementing them in health insurance

A matter of some significance to the United States is the decision of the council to implement an all Canadian program of hospital accreditation from Jan 1, 1959 Hitherto, Canada has been represented on the Joint Commission on Accreditation of Hospitals, whose headquarters are in Chicago, and has also run a Canadian Commission on Hospital Accreditation The following are several reasons why Canada should proceed alone 1 Canada is large enough and well enough organized to run its own program 2 It is better able to work with hospitals whose administrators speak French and with whom correspondence and negotiations must be carried out in French 3 It needs to have available such information, arising out of hospital inspection, as data on specialty training and intern training facilities 4 The intervention of provincial and national governments in hospital affairs makes an all-Canadian program desirable Therefore, the Canadian Medical Association, the Canadian Hospital Association, the Royal College of Physicians and Surgeons of Canada, and L Association des Médecins de Langue Française will operate a voluntary accrediting agency from the end of 1958, maintaining, however, friendly liaison with the United States Joint Commission and, at first, using the same standards.

The Committee on Medical Education rejected a suggestion for the establishment of a single postgraduate medical school in Canada and also the idea that the C. M. A. should play a part in the inspection of medical schools. The Committee on Maternal Welfare called for a total ban on the manufacture of preparations containing apiol, which is apparently being used as an abortifacient with occasional disastrous results. The Committee on Pharmacy introduced a resolution to the federal government that the newer tranquilizers be obtainable on prescription only.

Rheumatic Diseases.—In June, the Royal York Hotel, Toronto, was headquarters for the Ninth International Congress on Rheumatic Diseases. Smith (West Point, N. Y.) and Lockie (Buffalo) both believed gold therapy to be the treatment of choice in patients with rheumatoid arthritis. West (Sheffield, England) considered that adrenal stimulation with corticotropin was practically and theoretically superior to that with cortisone or analogous steroids in treating this disease. Currie (Glasgow, Scotland) uses subtherapeutic doses of steroid combined with subtherapeutic doses of pyrazoles and salicylates for rheumatoid conditions. Coste (Paris) believed prednisone to be the drug of choice in acute rheumatism. Riedl (Prague) reported beneficial effects in acute rheumatism from the anticoagulant drug, ethyl biscoumacetate (Pelentan). Gil (Mexico) considered steroids to be more effective than the salicylates in preventing cardiac complications in acute rheumatism. Traut and Thrift (Chicago) denied that therapeutic benefits from salicylates were due to an adrenotropic effect. Lafond and co-workers (Montreal) found phenylbutazone of value in osteoarthritis, particularly in monarticular forms affecting the knee. In most cases, rheumatic spondylitis also responded well to this drug. Patients with a variety of other orthopedic conditions, including osteitis deformans, gout, bursitis, and myositis, were also benefited by it. The effective dosage is lower than that generally used, and the drug is not curative but only palliative. Hart (London) stated that cortisone and aspirin gave similar results in patients with rheumatoid arthritis. Santamarina and co-workers (Havana) showed that, in general, the effects of prednisone or prednisolone were much the same whether the drugs were given intramuscularly or orally.

Brochner-Mortensen (Copenhagen) presented a follow-up study of 50 patients with rheumatoid arthritis treated with steroids for up to seven years. Eight did not respond, 8 had severe side-effects, and 27 were still being treated. Of the latter, 20 were able to work and only 1 was totally incapacitated. Slocumb (Mayo Clinic, Rochester, Minn.) described hypercortisonism in rheumatoid arthritis treated with steroids; this complication of therapy may include periarteritis nodosa, lupus erythematosus, and swings of mood from agitation to fatigue (likeliest seen in withdrawal periods or times of irregular administration). Batterman (New York) believed sesame oil to be responsible for many of the untoward reactions to gold therapy. Bunim (Bethesda, Md.) gave an alarming picture of the limitations of prednisone therapy in rheumatoid arthritis. There was a 24% incidence of peptic ulcer, and some deaths were attributable to the steroid in a series of 36 patients treated for up to two years. A daily maintenance dosage of 15 mg. should be the maximum. Another speaker recommended 10 mg. daily for men and 7.5 mg. for women and claimed a lower mortality and morbidity than that claimed by Bunim. Bagnall (Vancouver) was pleased with the results of the use of 0.5 Gm. of chloroquine daily for indefinite periods in patients with rheumatoid arthritis and spondylitis. Only 17 of 125 patients were unable to continue because of nausea or dermatitis. A possible alternative is hydroxychloroquine. Bruckner (Bucharest) confirmed the good effect of synthetic antimalarials; he had good results in 32 of 36 patients. Rinehart (Wheeler, Ore.) also praised use of chloroquine. Fischel (New York) advocated a combination of steroids and salicylates in acute rheumatism, but Milcu (Bucharest) combined an antithyroid drug with either the steroid or the salicylate. Barcelo (Barcelona) stated that phenylbutazone and prednisone acted synergistically in patients with rheumatoid arthritis.

In prophylaxis for gout, Talbott (Buffalo) recommended probenecid with colchicine; Gutman (New York) agreed that most chronic gouty arthritis can be prevented by probenecid and a salicylate, and Serre (Montpellier) found probenecid and phenylbutazone best for patients with chronic gout. Ogryzlo (Toronto) made a comparative study of uricosuric agents and found 4-(phenylthioethyl)-1, 2-diphenyl 3, 5-pyrazolidinedione the most effective. Marson (Leeds, England) considered sodium salicylate better than probenecid in the treatment of chronic gout. Neustadt (Louisville, Ky.) believed it likely that desacetylmethylcolchicine would replace colchicine in the treatment of acute gout. Robins (Buffalo) found phenylbutazone the drug of choice in patients with rheumatoid spondylitis and gouty arthritis but warned that concomitant cardiac disorders should be an indication for careful selection, close observation, and control of fluid balance. Boni (Zurich) believed that the antirheumatic effect of this drug is due to a lowering of the action potential in muscles.

Ambros (Warsaw) showed that abnormal electroencephalographic changes in rheumatoid arthritis disappear with salicylate therapy. Meltzer (Philadelphia) believed that the incidence of peptic ulcer in patients taking prednisone was no higher than in other patients. Mizraji and Ramos (Montevideo) have been injecting hydrocortisone intrathecally in certain patients with lumbosciatic pain, as have Lucherini and Cecchi (Rome). The latter obtained good results with this treatment in 80% of their patients. Kelly (Melbourne, Australia) believed that phenylbutazone was a specific antirheumatic drug and most useful for prolonged therapy in small doses after careful supervision for the first three months. Controlled trials in Stockholm by Fjallstrom proved the value of phenylbutazone in active rheumatoid arthritis. For scapulohumeral periarthritis, Saiach (Argentina) preferred stellate ganglion block with intra-articular hydrocortisone. Elek

(Budapest) used these two methods with suspension of the patient by the neck and shoulders in a thermal bath

DENMARK

Hospital Scarlatina —In 1947, Dr T Jersild reported that treatment with sulfonamides had no effect on hemolytic streptococci, but that after only six days treatment with penicillin, a bare 4% of the patients with scarlatina still harbored streptococci Since 1947 every patient admitted with scarlatina to the Blegdam Hospital in Copenhagen has been treated with penicillin To ascertain what effect this treatment had on the incidence of scarlatina among the nurses of this hospital Jersild investigated the incidence of scarlatina in the hospital nurses in the period 1938 to 1956 (*Ugeskrift for læger,* June 6, 1957) In the past the number of hospital infections with scarlatina fluctuated with the number of the admissions to hospital, and the low rate of such infections in 1938, 1941, and 1946 corresponded to a low admission rate for scarlatina The hospital infections showed no reduction in number during the period 1941 to 1945 in spite of the maintenance of consistent treatment with sulfonamides In 1947 and 1948, when every patient with scarlatina was treated with penicillin, the number of nurses who contracted scarlatina came down from 21 (1944) to only one (1947) and none in the following years

Surgical Menopause —In the *Danish Medical Bulletin* for May, 1957, Dr A Leth-Pedersen gives an account of 201 women who underwent bilateral oophorectomy between the ages of 17 and 39 years Most of them suffered from salpingo-oophoritis or ovarian cysts Only 150 could be regarded as completely castrated All were subjected to a follow-up examination after an average period of 11 4 years Hormone treatment had been given to almost every patient with surgical menopause under the age of 40, but only about 10% of the completely castrated women had received adequate hormone treatment In about 15% of these women sexual life had improved after the operation, and there was a rise of only 13% in the number of frigid women in the period between the operation and the follow-up examination This rise was not higher than can be expected of Danish women in general in a similar age group This and various other considerations make it highly probable that castration has no biological effect on the adult woman's sexual feelings with regard to intensity or capacity for orgasm At least 15% of the completely castrated women experienced rhythmically occurring somatic and psychic symptoms corresponding to the premenstrual tension syndrome in spite of the absence of menstruation

Cholecystitis —During the six-year period from 1945 through 1950 a total of 272 patients with cholecystitis were treated at the Odense County Hospital This series was studied by Lyndrup and Kristensen (*Ugeskrift for læger,* June 13, 1957) Of the 194 patients given only conservative treatment, 9 died, whereas there were 7 deaths among the 28 patients who underwent emergency operation on imperative indications There was only one death among the 50 patients who underwent elective operations From 5 to 10 years after discharge from hospital, a follow-up investigation was made of 199 of these patients, 44% were symptom-free and 24% were in relatively good health The remaining 32% were in poor health or had undergone an operation later, 17% had undergone operations on the biliary tract after discharge It was concluded from this study that (1) all patients suffering from marked cholecystitis should be admitted to hospital immediately, at the onset of the attack, (2) if conservative treatment is started, the patient should be kept under close observation by an experienced clinician, and (3) an operation is indicated for all patients who have suffered from cholecystitis on one occasion and have a history of gallstones but important contraindications to an operation must be considered with this reservation, that such contraindications imply a greatly increased risk of complications in a subsequent attack of cholecystitis When there is no previous history of cholecystitis, more restraint should be shown in advising operation, but immediate admission to hospital is always indicated if there is a recurrence of symptoms

Hypertrophy of the Breast —A series of 222 women who underwent operations for hypertrophy of the breasts during the six-year period from 1947 through 1953 at the Bispebjerg Hospital was studied by Dr Erik G Christiansen (*Ugeskrift for læger,* May 30, 1957) While much is now known about the causes of growth of a normal breast, the cause of breast hypertrophy continues to be obscure Hitherto activities in this field have been confined to pathological and anatomic investigations and certain operations None of the 222 patients had any signs of endocrine disturbances, but determinations of the estrogen content of the blood showed significantly high figures when the hypertrophy was still progressive, whereas the figures were normal when the development of the hypertrophy had come to rest In about half the patients the hypertrophy had started with the onset of puberty, and about 25% developed during pregnancy The onset of puberty as indicated by the first menstruation was relatively early, and in about 25% menstruation had been more irregular than in a control series In 45 patients there were similar cases in the patient s family In most patients the development of the hypertrophy was gradual, whereas in 59 the onset was acute Christiansen concurred in the opinion of earlier observers that hormone disturbances are a factor in the pathogenesis of breast hypertrophy

National Association for Diabetes —The annual report of The Danish National Association for Diabetes for 1956 shows how varied its activities are In the last six years it has contributed more than 70,000 kroner to scientific research It publishes a journal, issued five or six times a year, with the object of keeping diabetics up to date about the many dietary precautions they have to take Each member of the association receives this journal free of charge In 1956 the association's convalescent home, Dyrehavehus, admitted 304 diabetics, 72 of whom came direct from a hospital In the same year 147 diabetic school children spent three weeks in the association's holiday camp, where they were taught how to live as good diabetics In another home 19 diabetic children, aged 2 to 14 years, from poor homes were housed and fed In the summer of 1956, the mothers of diabetic children under school age were given a 10 days' training at one of the association's centers

INDIA

Urinary Tract Infections —W R Bett (*Current Medical Practice* 1 4 [April] 1957) stated that, in spite of the use of sulfonamides and antibiotics, certain urinary tract infections prove stubbornly resistant, especially those caused by Pseudomonas aeruginosa and Proteus vulgaris Nitrofurantoin acts by interfering with the enzymatic metabolism of the bacterial cell Given by mouth it is effective against both gram-positive and gram-negative organisms and also certain protozoa It is the treatment of choice for P vulgaris infections Treatment should be continued for 5 to 7 days at least for 3 days after the urine has been sterilized but for not more than 14 days The course may be repeated after an interval of four weeks If there is no obvious improvement within a week, it should be discontinued Its side-effects are minimal, consisting mainly of nausea and vomiting It can safely be used even for children and pregnant women

Indian Physicians for Malaya —A three-man selection board from Kuala Lumpur, Malaya will come to India in July to recruit physicians for the Malayan health services One of the members of the board is the director of health services in the federation and another a member of its public service commission Over 1,000 Indian physicians have applied for these appointments which will be limited to a period of three years The number of posts advertised by the Malayan Government is 100

Saccharated Iron Oxide —B B Guha (*Indian M J* 51 5 [May] 1957) stated that, although giving iron by mouth produces satisfactory results in most patients with iron deficiency anemias and although this treatment is simple, economical, and devoid of any risks, some patients fail to respond Such patients may be given iron intravenously The incidence of untoward reactions of varying severity observed during intravenous treatment with iron has prompted caution in its use The reactions may appear during administration or as late as six hours after the injection The late reactions are rare and occur only when large doses are used In order to minimize the risk of these reactions the injection should be given slowly, the initial dose should not exceed 25 mg , and increase in dosage should be gradual till a dose of 100 to 200 mg is reached The iron solution should be diluted with 5% dextrose or the patient's blood Very old ampuls should not be used

Anemia and Liver Damage —P S Vasavada and co-workers (*J Indian M A* 28 342 [April 16] 1957) reported that anemia is a common finding in patients with chronic parenchymal damage of the liver Nutritional deficiencies, malaria, amebiasis, tuberculosis, visceral leishmaniasis, and chronic intestinal disorders may produce such damage The authors studied patients with such conditions to find out whether there are differences in the type and degree of anemia in those with primary liver disease and in those patients with diseases known to produce patchy liver damage A total of 70 patients with portal cirrhosis, infective hepatitis, amebic hepatitis, and hepatomegaly associated with chronic malaria, tuberculosis, chronic bowel disease, leukemia, and secondary carcinoma of the liver was investigated The liver function was assessed by thymol turbidity, cephalin flocculation, colloidal gold test, prothrombin response to vitamin K, urinary urobilinogen estimation, icteric index, and van den Bergh's test Half of these patients showed macrocytic anemia irrespective of the type of liver damage No correlation was observed between the degree and variety of anemia and the type and extent of derangement of liver function

Serum Cholesterol and Phospholipid Levels —H P Nath and co-workers (*Indian J M Res* 45 2, 1957) stated that there has been an increasing incidence of coronary disease in the armed forces of India in the last few years Among the factors studied, a change in the lipid metabolism, specially that of cholesterol metabolism, has been implicated most consistently in the pathogenesis of this disease Because of this close association of hypercholesteremia and coronary disease, the authors studied the cholesterol metabolism in normal Indians of various age groups, 25 men from each of the age groups 21 to 30, 31 to 40, 41 to 50, and 51 to 60 years were selected Each subject was examined to rule out the presence of any disorder likely to upset the fat metabolism Each group contained 15 nonvegetarians and 10 vegetarians Height, weight, chest and abdominal girth, serum cholesterol level, blood phospholipid level, and blood pressure were measured The cold pressor test was used to discover hyperreactors The total serum cholesterol content of the above different age groups was found to be 177, 195, 208, and 215 mg per 100 cc respectively These readings were almost the same as those reported for Europeans and Americans but were slightly higher than those reported by other workers for Indians The cholesterol level increased with age and weight but was not affected by smoking, alcoholic habits, or racial differences The average reading for nonvegetarians was 16% higher than that for vegetarians The ratio of total cholesterol to lipid phosphorus was almost the same for all age groups The lipid phosphorus content was slightly less in the 21-to-30 year age group The blood pressure readings in all the subjects were within normal limits, but 20 were found to be hyperreactors by the cold pressor test These 20 showed relative hypercholesteremia It would be interesting to know the incidence of coronary disease in these hyperreactors

Salmonella Typhi—M Savitri and co-workers (*J Postgraduate Med* 3 2, 1957) tested 663 Salmonella typhi strains (586 from Bombay, 70 from Amritsar, and 7 from Poona) for bacteriophage typing Ten of the 33 Vi bacteriophage types and subtypes were identified during this study The most common types in Bombay according to their decreasing order were A, O, E1, D1, J, K, T, D6 (single case), and 28 (single case) The most common types at Amritsar were A, D1, O, E1, T 28 F1 (single case), and K (single case) Attempts were made at identifying new bacteriophage types by adapting bacteriophage A on untypable Vi strains and were successful in two instances The two newly adapted bacteriophages and their homologous cultures were sent to Dr Felix, chairman of the International Committee for Enteric Phage Typing, London for confirmation Of the 54 untypable Vi strains isolated at Bombay, Amritsar, and Poona, 11 were found to react similarly to these new Vi bacteriophage types Attempts were also made to determine the parent strains from degraded Vi strain by plating out the culture and subjecting the isolated colonies to routine typing tests Antibacteriophage serums against bacteriophages I, II, and IV were prepared in rabbits for testing the purity of the specific bacteriophages and also of any bacteriophage that might be newly prepared by the process of adaptation of bacteriophage II to untypable cultures Thus in this study two new Vi bacteriophage types, namely 801 and 835, were discovered Type 801 was isolated from Bombay It was responsible for three cases of typhoid fever in Bombay Bacteriophage type 835 was isolated at Amritsar Further studies showed that Vi bacteriophage type 835 was responsible for six cases of typhoid fever in Bombay and one in Poona Due to lack of information, no link to a carrier in these cases at Amritsar, Bombay, and Poona could be established The study emphasizes the need for routine bacteriophage typing of S typhi, this would go far in helping to eradicate this common disease in India

Drug Combination as a Communication Facilitant—K J Bhaskaran (*J Indian M A* 28 10, 1957) stated that the uncommunicative patient has always been a problem to the psychiatrist Two of the drugs widely used to facilitate communicativeness are amobarbital and methamphetamine hydrochloride, used separately or in combination and usually by the intravenous route When amobarbital alone is used, the patient often falls asleep, and when methamphetamine is used alone, it often produces unpleasant side-effects These are much less severe when a combination of the two drugs is used The author used this combination on 40 uncommunicative psychotic patients Special attention was focused on the degree of relaxation, change of mood, degree of motor activity, degree of communicativeness, degree of rapport, and untoward side-effects The combination was most effective in psychoneurotic, depressed, pseudoneurotic schizophrenic, schizoaffective, and paranoid schizophrenic patients in that order Those with catatonic stupor showed limited or no benefit Those with marked anxiety were benefited much more than those showing limited or no anxiety Those who were originally communicative but later lapsed into a mute state were often helped by this combination No major side-effects were noticed except nausea, vomiting, and sleeplessness on the day of injection

Rural Medical Relief—A medical relief and public health camp was set up at Alamadi, about 15 miles from the city of Madras, by the Rural Medical and Social Service League of the Stanley Medical College Association Situated in the center of a cluster of villages, this camp serves a population of about 20,000 A dispensary is run every day at the camp between 3 and 6 p m, and public health work is undertaken in the mornings The camp staff of 55 includes 2 physicians 7 social workers, and 2 vaccinators A dentist visits the camp once a week Nutritional, general, economic, and family planning surveys have been made in seven villages and will be undertaken in eight more Multipurpose food and milk are supplied free to the people twice daily

JAPAN

Asian Influenza—An epidemic of influenza is spreading throughout Japan Although it is regarded as a mild type, many schools are closed down because 10% or more of the students are absent due to sickness Fear is felt that another wave of influenza of greater intensity will follow, because the so-called A type Tokyo strain confers only negligible immunity A vaccine should be available early in November The aged and infirm will be the first to receive the injections

Cancer—The Bureau of Public Health and Welfare reports that the highest death rate for 1956 was due to cardiovascular diseases and that cancer was a close second Pulmonary tuberculosis, formerly in first place, now ranks fourth Gastric cancer was the commonest type of cancer by far in both men (55% of the total) and women (36% of the total)

State Medicine—If our present system of socialized medicine continues, it will soon become bankrupt and the health and welfare of the people will be in jeopardy Although the hospital physicians are required to work for substandard wages, there is something even greater at stake If the 80 million people can be medically cared for under the present budget, the physicians of Japan will gladly make sacrifices but, unfortunately, standards of medical care have sunk to the lowest level in history Since 1950 the price of necessities has steadily climbed upwards, but for over six years the pay of physicians has remained the same They have repeatedly asked for revision of their pay scale, but nothing has been done Dr Edwin L Crosby, of the United States, was invited last fall to investigate the situation In his report he stated that all difficulties found in the way of socialized medicine stem from inadequate finances Specifically for each patient cared for the hospital receives $1 00 per day regardless of quality of care or cost of medication This rate has not been changed in the past six years

So long as the present difficulties remain unresolved, despite the sacrifices made by the hospital personnel Japan's medical advance will fall behind that of the rest of the world

NEW ZEALAND

Asian Influenza—The Auckland Medical Officer of Health reports that the Asian-type influenza has been kept at bay Although the number of cases for June was higher than that for May, it was much lower than that for June of either 1956 or 1955 It seems unlikely that the Asian influenza is present in Auckland in epidemic proportions No virus similar to the Asian strain has been isolated from any indigenous case Precautions have been adopted to check early cases among ship's crews It has been reported from Sydney, Australia, that more than 100 crew members of an Australian aircraft carrier caught Asian influenza while the carrier was in Hong Kong The medical officers on board said that the only reason Asiatics died from Asian influenza was because they were undernourished and their resistance to disease was low Among the crew members of the carrier, the disease appeared as a mild influenza lasting only two days The present epidemic of influenza sweeping through parts of Asia does not appear to be more serious than the usual epidemics that annually affect New Zealanders The present attitude of the New Zealand health officers is that there is no need for alarm

Closing of Tuberculosis Sanatorium—The Minister of Health has closed the Waipiata Sanatorium The reasons given were a dearth of patients, difficulty in maintaining a staff, and the fact that funds used to run the sanatorium could be better spent elsewhere About $600,000 a year (for a total New Zealand population of 2 million) is being spent by the health department in the campaign against tuberculosis If the total amount spent by the state through the hospital boards is included, the figure is about $3,000,000 a year As recently as 1952, 226 persons of European stock died from pulmonary tuberculosis In 1956 only 142 persons died The rates for these two years were respectively 12 and 6 9 per 100,000 population This laudable achievement was due to the improvement in therapy

Drug Bill—New regulations to control expensive prescribing under the provisions of the Social Security Fund and to control claims for the excessive number of general medical services provided by Social Security are in preparation The Minister of Health has released the report of a special committee set up to investigate pharmaceutical benefits under the Social Security Fund The committee found that over the period 1947-1956, while the population of New Zealand increased by 21 4%, the increase in the cost of pharmaceutical benefits amounted to 181% This increase was due principally to the rise in the number of prescriptions per person per annum and to the rise in the average cost of prescriptions Over this 10-year period the number of prescriptions per person increased by about 56% It was clear that people had been seeing their physicians more frequently each year The drug bill has mushroomed from $4,500,000 in 1948 to $12,000,000 in 1956 The trend is the more serious in that the cost increased 27% in a few months The committee examined in detail all the factors which were believed to have contributed to the rise in expenditure on these benefits, and, of these, the general rise in cost and the introduction of new and expensive methods of treatment in recent years were the principal factors The committee reported that a great saving might be effected by the remission of customs duty on items specified in the drug tariff It recommended that a charge on prescriptions be introduced at a flat rate for each prescription, exemptions to be granted on economic grounds rather than in regard to specific ailments, that regulations to control excessive prescribing and claims for an excessive number of general medical services be introduced, that the question of the desirability of improving the training of medical students in regard to prescribing be taken up with the authorities concerned, that surveys be carried out regarding the extent of telephone prescribing in large towns as compared with rural areas, and that efforts be made to discourage telephone prescribing

The fact that physicians are becoming more freely available has contributed to the increase in the number of services given per capita This, in turn, has increased the number of prescriptions issued An appreciable factor in steadily rising costs resulted, paradoxically from the success of modern scientific treatment New and effective drugs have become available for the treatment of conditions of formidable character and conditions liable to serious complications In the case of chronic diseases, the product used is often a substitute for some inherent deficiency and must be given regularly for the remainder of the patient's life In either case the cost of the drugs themselves is often high but must be thought of in terms of what is achieved in the alleviation of suffering and the reduction in loss of time from work The antibiotics which contributed largely to the most recent sharp rise in costs come under both headings There is no doubt, however, that they have been used unnecessarily and extravagantly in many cases An increased awareness of the Social Security charge and exaggerated notions about the part represented therein by pharmaceutical benefits has been noticeable in the attitude of many patients in recent years Such people often expect to be given prescriptions for simple household remedies, like aspirin, which a few years ago they would have purchased for themselves

Some basic proposals put forward by a group of Auckland physicians (*New Zealand Medical Journal*, Feb, 1957) for a reorganization of the service have not been accepted by the Central Medical Services' Advisory Committee The whole scheme put forward by these doctors was considered by the British Medical Association If necessary, the Minister of Health will arrange for the committee to consider the question again after the B M A 's recommendations are known The committee does not accept the central and most important feature of the group's scheme which proposed that the state pay $2 for each of the first 25 patients attended by physicians under the social security and 30 cents for each additional patient but that a physician whose optimum is higher than 25 patients should be able to choose the state's subsidy from one of several sliding scales and to review the optimum annually

Other facts to be considered are that the social security medical services are here to stay, that the public at large has come to demand an elaborate issue of free medicine, and that repeated appeals to the physicians and the mild forms of restraint so far applied have achieved little It is against this background that the onus is on the government to find a means of reducing the $6 per capita in relation to the resources available The biggest hope for a worthwhile improvement is in the introduction of a charge on prescriptions The argument for it is that a nominal charge—about 14 cents is the amount imposed for all prescriptions in Great Britain—would serve the double purpose of making prescription addicts think twice before badgering their doctors for refills or something new" and bring about a substantial saving in the total bill for benefits It can be forecast confidently, however, that the government will not implement the introduction of the flat rate for prescriptions It is understandable that the imposition of a charge in any form is an unpalatable political prospect, particularly in an election year Alternatively, the government will have to devise a scheme for supporting the "free medicine' bill

Experimental Aortic Surgery—Dr J Borne (*Proc Univ Otago med Sch* 35 6, 1957) reported that the ideal method of treating aortic regurgitation is competent vascular reconstruction in the ascending aorta, preferably proximal to the coronary arteries Pilot experiments on sheep showed the feasibility of placing an annular constricting suture around the aorta proximal to the coronary arteries but emphasized dangers in dissecting the coronary arteries and sinuses of Valsalva A specially designed forceps was used, the right coronary artery was approached by a sternal splitting incision, and a double no 4 silk ligature was passed beneath it The left coronary artery was approached by left thoracotomy, the ligature was brought around between the aorta and pulmonary artery in front, through the transverse sinus behind, and tied After this preliminary operation, 3 of 10 animals recovered Of the remaining seven, the operation was abandoned in two because of hemorrhage of the sinus of Valsalva Two died from injury to the coronary arteries, one from ventricular fibrillation, and in two the suture rode up and occluded the right coronary artery at its origin Although an annular suture can be placed around the aorta in sheep, it cannot be recommended in man because of the vulnerability of the right sinus of Valsalva and the right coronary artery and the tendency for the suture to ride up and occlude coronary circulation

Radioactive Fall-out—Suspicions that New Zealand is being subjected to abnormal radioactive fall-out through a possible pollution of the atmosphere by cumulative nuclear weapons tests have been aroused in R Borthwick and J Tait, physicists at the Christchurch Hospital By using the sensitive Well scintillation crystal, they traced what they believe to be an abnormal amount of decaying radon gas and something with a much longer half-life in rain water This observation, however, is not conclusive, as there is no New Zealand reference level of normal radioactivity determined by this method The use of the Well scintillation crystal is quite a different method from the electrostatic precipitation method by which the Dominion X-ray Laboratory had earlier monitored for radioactive dust in the atmosphere Mr Borthwick has concluded that something abnormal has come into the atmosphere, not as a direct result of the recent British nuclear weapon tests on Christmas Island in the Pacific, but by the cumulative effects of the many tests made in the last few years The effects, so far, are apparently not serious, but they could be There is now an international recommendation that rain water should be sampled for fall-out

SWEDEN

Spiritual Welfare of Hospital Patients—In the March 9 issue of THE JOURNAL, an account was given of an experiment recently made in a public Swedish hospital in which a clergyman wearing the robes distinctive of his calling was allowed to join the physicians in their hospital rounds On one such occasion a woman patient, whose surgical dressings had to be changed, made no complaint at the time but waited till she left the hospital, when she launched a campaign against what she considered an outrage and of which she furnished the sensational lay press with a harrowing description This incident led to questions being asked in the Swedish Parliament The Communist press gave a lurid account of clergymen masquerading as physicians, wolves in sheep's clothing, peeping Toms thirsting for a sight of naked limbs As a result what had seemed to be a promising experiment came to an abrupt end

Leptospirosis—Of the 40 serologically different types of leptospirosis, the one that has hitherto been most prevalent in Sweden has been leptospirosis icterohemorrhagiae (Weil's disease) At the Virus Laboratory of the Sahlgren Hospital in Gothenburg, serologic tests have been made for years as a matter of routine for leptospiral infections giving rise to serous meningitis In the autumn of 1952 this vigilance was rewarded by the discovery of two cases of leptospirosis with the Sejro type, named for a Danish island in which this type was first identified Describing these two cases in detail in *Svenska lakartidningen* for Feb 15, Dr Afzelius-Alm and co-workers pointed out that, though these were the first cases to be reported in Sweden, they did not necessarily represent a rare condition Both patients responded well to penicillin, but it is probable that most such cases end in spontaneous recovery after a short bout of fever It may be impossible by clinical examination alone to distinguish between a viral and a leptospiral meningitis, and only a serologic examination may confirm the diagnosis In the acute phase of leptospirosis serologic tests are likely to prove negative, and they may not be positive till the patient convalesces The impression that leptospirosis must lead to jaundice is so general that it is well to keep in mind the possibility of its absence, the clinical findings being those of an acute benign meningitis with absence of reflexes and paretic muscles suggesting an attack of acute poliomyelitis

Smoking Habits and Pulmonary Disease—Reference was made in THE JOURNAL for Jan 26 to an investigation by Dr B Ejrup into the capacity of injections of lobeline to break the tobacco habit His findings were so encouraging that they led Dr G Sterky (*Svenska lakartidningen*, May 3, 1957) to repeat his experiments on patients in a chest hospital The first step was to approach, by means of a questionnaire, 330 patients Answers about their smoking habits were obtained from 198 men and 80 women Many of them had already reduced their smoking of cigarettes by about half and wished to be able to smoke still less Thirty-eight patients volunteered to submit to subcutaneous injections of lobeline twice a day and for 10 days Of these, 20 were given lobeline and 18 received injections of an isotonic saline solution put up in ampuls indistinguishable from those containing lobeline Though Sterky's results were not as encouraging as Ejrup's, they were good enough to warrant repetition Nine of the 20 patients receiving lobeline reduced or stopped their smoking, but of 18 patients given the placebo the smoking habits of 13 were unaltered

Traffic Accidents—At the meeting of the Northern Surgical Congress in Stockholm in June an analysis of 20,000 traffic accidents was presented In 77% of these accidents the victims had been traveling at less than 60 km per hour (about 40 mph) In most of these cases the skull or patella had been fractured, and 30% of the patients were less than 20 years old Ambulances came in for searching criticism with complaints of noisy and reckless driving calculated to defeat the primary object of an ambulance service

Asymptomatic Tularemia—A curious feature of the 814 cases of tularemia reported during the period 1931 to 1956 is their almost complete concentration in two adjoining counties in Sweden In the summer of 1953, Dr O Ljung (*Svenska lakartidningen*, June 7, 1957) working in one of these counties studied atypical and abortive forms of tularemia by means of intracutaneous tests with dead Pasteurella tularensis Of 40 persons who had had tularemia 2 to 21 years earlier, 36 gave a positive skin reaction, whereas no positive reactions were observed in 131 persons living in areas in which tularemia was unknown On the other hand, in the two tularemia-infested counties, positive reactions were obtained in 227 of the 2,047 persons who were never known to have suffered from tularemia This suggests that abortive and asymptomatic forms of tularemia may be common in tularemia-infested areas As the intracutaneous reaction may continue long after the original infection, positive reactions do not mean that a patient is suffering at the time from an attack of the disease Though little is yet known about the incidence of tularemia throughout most of Sweden, it is clear that at least 10% of the adult population of a tularemia-infested area give positive reactions to intracutaneous tests

UNITED KINGDOM

Influenza Vaccine—In November, 1951, the Medical Research Council set up a committee to arrange clinical trials of influenza vaccine The committee has made its third progress report based on trials conducted between 1954 and 1956 (*Brit M J* 2 1, 1957) In the winter of 1954-1955, serologic and field trials of three virus A influenza vaccines made from the strain A/Eng/1/54 were carried out One vaccine was a saline egg-line vaccine with aluminum phosphate, and the other two were emulsified vaccines made from egg-adapted and mouse-adapted viruses The control was a virus B vaccine (Lee strain) The antibody response was maximal within a month in persons inoculated with the saline vaccine and in three months after inoculation with the emulsified vaccines, although in the latter case it reached a higher value The mouse-adapted emulsified vaccine gave a lower antibody rise than the egg-line vaccine Antibody levels were higher one year after inoculation than they were before the vaccine had been given A field trial of these four vaccines was carried out on 14,708 volunteers in 69 industrial communities The incidence of influenza was low and was mainly influenza B The absence rate due to influenza was practically the same in each vaccinated group and ranged from 5 0 to 5 8% In a follow-up of the 12,890 persons who remained in the same employment in 1955-1956, the absence rates ascribed to influenza were again low, and no difference was detected between the four groups

In 1955-1956 a further serologic and field trial was made with two saline vaccines (a monovalent one from the strain A/Eng/19/55 and a polyvalent one from strains PR 8 and FM 1 and swine) with virus B vaccine as the control The monovalent vaccine increased the antibody titer in volunteers 30 years old and over to a uniform level against all the viruses used, except the 1956 strain To its own antigen, an exceptional response occurred In volunteers 25 years old and under, the result was similar except that a lower response to swine virus occurred The general effect of the polyvalent vaccine was to reinforce the antibody levels present before inoculation A vaccine made from a strain from a virus isolated in 1956 produced lower levels than any other vaccine These three vaccines were administered to 7,495 volunteers in industrial areas and to 5,278 from the Royal Air Force Significantly smaller absence rates from influenza occurred in those volunteers vaccinated with the A vaccines than in those vaccinated with the control vaccine The advantage of the A vaccines over the B vaccine was most apparent during the period when influenza A was prevalent Protection given by the monovalent virus A vaccine was of the same order as that provided by the polyvalent vaccine The saline virus A vaccine used in the 1954-1955 trials caused an excessive number of general and local reactions as compared with other vaccines A small number of more serious and often delayed local reactions occurred in 0 2 to 0 5% of those who received the emulsified vaccines

The Public Health Laboratory Service reported to the Medical Research Council on the state of influenza in the United Kingdom between 1953 and 1956 Morbidity and mortality statistics taken in conjunction with laboratory results show that no severe epidemic of influenza occurred in the United Kingdom in this period though influenza B was prevalent in most parts of the country in the winter of 1954-1955, and influenza A was prevalent in the winter of 1955-1956 Localized outbreaks and sporadic cases of influenza A were detected fairly often in the first half of 1954 and 1955, and sporadic cases and minor outbreaks of virus B infections were detected in the late winter of 1953-1954 and less frequently since the large epidemic that followed Most of the virus A infections in 1953-1956 were probably due to virus of the Scandinavian group Influenza virus B strains isolated during the 1954-1955 epidemic differed antigenically from earlier strains of this group The frequency with which respiratory illnesses associated with influenza A and B infections were detected between epidemics suggests that both infections are endemic in Great Britain

Age for BCG Vaccination —The age recommended for giving BCG vaccine to children is 13 years, but Pollock (*Brit M J* 2 20, 1957) questions whether this is the optimum age Using the Registrar General's reports, he investigated the morbidity from tuberculosis among children below the age of 14 and found that a substantial number of school children have already been infected with tubercle bacilli when they reach this age The annual number of new cases reported in children under 14 is 5,122, which corresponds to an infection rate of 1% of the existing population of school children This figure does not take into account the undiagnosed and unreported primary cases which are estimated from mass radiography surveys to be 22 per 10,000 persons in the age group under 14 or three to four times the number reported A primary tuberculous lesion causing minor or no symptoms and remaining undiagnosed and unreported in childhood may produce high morbidity later At between 5 and 10 years of age, the immediate dangers of primary tuberculosis are less than at other periods of life, whereas puberty and adolescence are periods of relative danger Pollock therefore believes that children should be protected by vaccination before the age of puberty The available evidence suggests that protection by BCG vaccination is prolonged and he therefore thinks that vaccination at 10 rather than 13 years of age would give the greatest possible protection He does not advise the vaccination of infant noncontacts, because this entails interference with the tuberculin test, which is so useful in case finding and epidemiologic studies

Attempted Suicide with Tranquilizing Drugs —Douglas and Bates (*Brit M J* 1 1514 [June 29] 1957) reported the case of a woman who consumed 290 25-mg tablets (7 25 Gm) of chlorpromazine Within an hour she was drowsy, confused, ataxic, and in shock Her stomach was washed out and 60 mg of methamphetamine hydrochloride was given intravenously and repeated one hour later, 500,000 units of penicillin was given every six hours, and 0 6 mg of atropine and picrotoxin were also given After a stormy period of three weeks the patient recovered Congestion and effusion of the lungs occurred in spite of the use of penicillin Heberden and Cooper reported, in the same issue, the case of a 30 year-old man who attempted suicide with meprobamate He took 8 Gm as a single dose one night and the next morning was found unconscious, with low blood pressure flaccidity of all limbs, and absent tendon reflexes He appeared to be in a state of hibernation with muscular relaxation and complete depression of the central nervous system After gastric lavage and an intravenous injection of pentylenetetrazol (Leptazol) he recovered and was normal by the next day

Anti-Deafness Drive —The Ministry of Health, in co operation with the medical profession, has launched a drive against deafness A memorandum sent to more than 20,000 family physicians states there are about 115,000 severely deaf and 1,659,000 moderately deaf people in Great Britain Many diseases that cause deafness are preventable and others are remediable if treated vigorously and early enough In other conditions, the worst effects could be mitigated by special training and the use of a hearing aid Ear, nose, and throat disorders accounted for the largest number of rejections from military service This indicates that many young people are either not seeking treatment soon enough or not persevering with it The family physician can do much to prevent this state of affairs The memorandum has been approved by the Central Health Services Council and distributed to physicians by local executive councils of the National Health Service

Smoking and Lung Cancer —In its annual report for 1955-1956, the Medical Research Council devotes a section to a review of the relationship between smoking and lung cancer This is the first occasion on which the council has expressed an opinion on the subject, and an abbreviated version of this section was distributed to the medical and national press This version was accepted by the government as a basis for taking action to draw the attention of the public to the dangers inherent in cigarette smoking The council believes that, so far, no adequate explanation of all the evidence indicating an association between cigarette smoking and cancer of the lung has been advanced except that of direct cause and effect and that smoking is, indeed, an important factor in the causation of the disease From the physical and chemical points of view, there is nothing inherently improbable in this interpretation Discrepant findings concerning the production of skin tumors in mice by applying cigarette smoke tar are not altogether surprising Tobacco smoke is a most complex mixture About 100 constituents have been identified with greater or lesser degrees of certainty There must be many more not yet identified, and the composition of the smoke may be expected to vary with the type of tobacco, the method of smoking, and the temperatures attained by the burning of tobacco In view of the equally discrepant findings on 3,4-benzpyrene, it may be supposed that a case was made out incriminating this carcinogenic substance in tobacco smoke as a causative agent in lung cancer, but closer examination leads to the conclusion that this supposition is not proved The amount of 3,4-benzpyrene in the smoke from 100 cigarettes is about one thirty-millionth of an ounce, about one-fifteenth of this probably comes from the paper and the remainder from the tobacco Even though this substance is known to be a powerful cancer-producing agent, there is no certainty that it is harmful in such low concentration Another weakness in the evidence lies in the nature of the biological test The fact that a given material will produce skin cancer in mice or rabbits is far from being presumptive evidence that the same material can cause lung cancer in man

Many factors, other than tobacco smoke, also are undoubtedly capable of producing lung cancer in man At least five industrial hazards have already been recognized and there is evidence that there may be others Studies of air pollution that suggest an association with lung cancer have been reported Stocks and Campbell, for instance, showed that most deaths from lung cancer in the semiurban and rural areas outside Liverpool can be attributed to smoking, but in Liverpool itself about 38% of the cases may be due to some other factor such as a general atmospheric pollutant Doll and Hill's data, on the other hand, failed to show any evidence of a substantial difference in the risk among nonsmokers in Greater London and in rural areas The particular kinds of atmospheric pollution suspected as causes of lung cancer are exhaust fumes from gasoline engines and diesel engines, as well as smoke from chimneys Again, the evidence is conflicting, and the council notes the suggestion of R L Cooper (1953) that the solvent action of some of the known constituents of tobacco smoke might remove the 3,4-benzpyrene from the soot deposited in the lung and bring it into intimate contact with the tissues In this way, the tobacco smoke and the atmospheric pollution could reinforce one another Or it may be that the additive effect of these various sources of cancer-producing substance (which is not necessarily entirely, or even mainly, 3,4-benzpyrene) is sufficient to turn the scale and produce cancer when one of these sources alone would be harmless On the day after publication of all this information—and the national press let themselves go on the subject—the shares of the leading tobacco company on the stock market showed a slight rise

The publication of the Medical Research Council report was immediately preceded by the publication of the first annual report of the tobacco manufacturers' standing committee The main points in the manufacturers' report are the following In the main-stream smoke from British cigarettes, smoked under normal conditions, 3,4-benzpyrene is present to the extent of about 3 to 5 mcg per 500 cigarettes This is equivalent to about 0 2 ppm by weight in the smoke or 0 01 ppm by weight of the tobacco smoke consumed The cigarette paper contributes, at the most, only about 10% of the benzpyrene found in the main-stream smoke From a limited series of experiments, it appears that pipe smoke contains at least as much benzpyrene, weight for weight, as cigarette smoke The daily intake of benzpyrene from breathing the air in a west country town was equivalent in total volume to the intake from smoking about 40 cigarettes a day, that from breathing London air is equivalent in total volume to the intake from smoking about 100 cigarettes a day Extensive research failed to confirm the claim that cigarette smoke contained about 1 part of 1,2,5,6-dibenzanthracene per 10 million parts of tobacco smoked The average arsenic content of British cigarette tobacco, in 1956, was only 7 ppm This means that the arsenic inhaled by a cigarette smoker today is not more than 0 3 ppm of tobacco smoked

In reference to published work on the subject, Sir Ronald Fisher said that from the point of view of experimental design the observations must, at this point, be criticized severely in that there has been no random experimental evidence such as is needed when dealing with flies or rats in drawing inferences of causation The smoking classes are self-selected No studies have been made as to what external or internal causes are effective in determining whether a subject shall be a nonsmoker, a pipe smoker, a cigarette smoker, or a cigar smoker We ought to be clearly and explicitly aware either of the principal causes in this field or of our ignorance of what causes are in action It would be incredible to assert that these smoking classes are not systematically different, at least in respect of genotype if not also in respect of environmental exposures not irrelevant to the subsequent incidence of cancer The importance of genotypic differences is familiar to workers in cancer research in mice and has been emphasized in man by recent findings of the association of blood-group A with cancer of the stomach In this case, it happens that an easy serologic test distinguishes the one class of genotypes from another, and the case makes it probable that any other genotypic separation, whether we can recognize it or not, would also be associated with different rates of cancer incidence

WORLD HEALTH ORGANIZATION

New Influenza Virus—The new virus responsible for the present widespread influenza epidemics in Asia has now been imported into the Netherlands, Australia, and possibly San Francisco, although this has not yet been proved by laboratory tests It is officially classified as virus A/Singapore/1/57, because it was first identified by laboratory tests in that city All reports continue to stress that the disease caused by this virus remains mild, running its course in about one week Very few deaths have been proved to be due to this cause, and these were mostly among elderly people suffering from chronic bronchitis There is still no specific cure for influenza, as the virus does not respond to antibiotics or other treatment, but penicillin and similar drugs remain the weapon of choice against such complications as pneumonia which may arise in the course of the disease In order to prevent further outbreaks of this new type of influenza, vaccine is being produced in several countries starting from virus specimens collected and distributed by the World Health Organization (WHO) to its 57 influenza centers in 46 countries The work is coordinated by WHO's World Influenza Center in London and the International Influenza Center for the Americas in Montgomery, Ala

WHO believes that it is impossible to stop the spread of influenza by quarantine, because such measures are as costly as they are ineffective There should be minimum interference with world traffic, although acute cases should be isolated The epidemic situation changes rapidly The disease has spread to most areas of Japan, Indonesia, the Philippines, Thailand, Laos, India, Pakistan, Iran, and Burma It is abating in Cambodia, Sarawak, Borneo, Formosa, and Viet Nam In the epidemic area, Korea, Dutch New Guinea, Ceylon, and East Pakistan remain untouched by the epidemic

Two new strains of influenza virus, similar to the Asian strain now causing widespread epidemics in the Far East, have been isolated from the crew members of two vessels of the United States Atlantic fleet Neither the two vessels involved nor their crews had had any contact with the Asian epidemic area Other vessels in the Atlantic report outbreaks of respiratory disease, but no virus has yet been isolated In Leyden, Netherlands, a clear case of influenza was contracted as a result of laboratory contamination It occurred in a laboratory worker handling ferrets infected with a virus of the Asian strain This shows how infectious this virus is for human beings This same laboratory reports that antibodies against the new virus are found only in the blood of older people (between 70 and 84 years of age) and hints that this might mean that the current Asian influenza is related to the virus that caused the great pandemic in 1889 Outbreaks of the disease are reported among crews of ships in the ports of London and Bristol Sporadic cases among air passengers arriving in England from Asia have also occurred, but there are no secondary cases and no evidence of local spread In the Netherlands the epidemic is spreading rapidly, and the virus is definitely identified as A/Singapore/1/57 The outbreak started in a girls' school near Amsterdam and spread to Naarden, Utrecht, Rotterdam, Amsterdam, and Egmond There are many cases, particularly in schools, with up to 100% of the children being affected There has been one death from a complicating micrococcic (staphylococcic) pneumonia in a 15-year-old child In Czechoslovakia three strains of the new virus have been isolated and shown to be different from any A strain previously identified there, but direct comparison with the Asian virus has not been completed On its westward course, influenza is now also reported in Teheran, Bahrein, Kuwait, Aden, and Yemen

Poliomyelitis —Cases of acute poliomyelitis increased in most countries of the world during the period 1950-1954, but this increase was uneven and deaths caused by the disease, although more numerous than previously, did not follow the same upward trend, according to a statistical report of the World Health Organization (WHO Epidemiological and Vital Statistics Report, vol 10, no 3, 1957) Nearly everywhere in Europe and America, 1952 was a record year for poliomyelitis, and during the whole five-year period the disease killed relatively more men than women In Europe (excluding the Eastern countries) there were serious outbreaks, and although fewer cases occurred there than in the United States (with only half the population of the 23 European countries concerned), the mortality in the United States was much higher Most severely hit in 1950 were Norway and Sweden (with death rates per 100,000 inhabitants of 303 and 224 respectively), in 1951 Norway again (death rate 628) and Switzerland (death rate 183), in 1952 Denmark (death rate 607), in 1953 again Norway (death rate 324), and in 1954 Switzerland (death rate 227) The lowest death rates in 1950 were recorded in Belgium (28 per 100,000), in 1951 in Denmark (2), in 1952 in Scotland (23), and in 1953 and 1954 in the Netherlands (8 and 3 respectively) Figures for 1955 are incomplete and indicate a decrease in some countries and a slight increase in others In the Americas serious outbreaks also occurred in the period under review, particularly in Canada in 1952 (4,755 cases and 311 deaths) and in 1953, which was a record year for that country (8,888 cases and 481 deaths) In the United States 1952 was the worst year, with 57,879 cases and 3,145 deaths As with other diseases, cases reported to the health authorities usually represent only a fraction of the existing cases Death statistics are more complete and consequently more exactly comparable between countries

Smallpox in Sudan —To combat an outbreak of smallpox in Port Sudan, WHO arranged for an emergency shipment of 125,000 doses of dried smallpox vaccine from Italy A further 125,000 doses was sent later The smallpox outbreak began on June 9 when two suspected cases were reported at Port Sudan on the Red Sea On June 22, 7 cases were reported, on June 29, 32 cases, and on July 6, 10 cases with two deaths Port Sudan is an important transit point for pilgrims on their way to Mecca in Saudi Arabia The information received does not indicate whether the outbreak is connected with the movement of pilgrims, and reports from Saudi Arabia do not mention any smallpox cases having occurred during the first days of this year's pilgrimage The last appearance of smallpox in Port Sudan was in November, 1949, in a pilgrim returning from Jidda

Regional Office for Europe —A new building erected by the Danish government, the WHO Regional Office for Europe, hitherto housed in the Palais des Nations, Geneva, has been opened in Copenhagen It is the directing and coordinating office for the work of WHO in 29 European countries together with Iceland and Morocco Thus the territory covered by this regional office stretches from the Atlantic to the Pacific oceans and is comprised of states which differ widely in their climatic conditions and social structures The new building adjoins the Tuberculosis Research Office of WHO, which has been established in Copenhagen since 1949

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Res Ipsa Loquitur: Sufficiency of Evidence to Overcome Inference of Negligence.—This was an action for damages against three physicians, a hospital, and a surgical nurse for injuries caused by their alleged negligence. The case against two physicians was settled. Motions for nonsuit were granted as to the hospital, the nurse, and the other physician, Eiskamp. The plaintiff then appealed to the Supreme Court of California.

After an operation performed by the defendant physicians, the plaintiff complained of pain. Subsequently, an x-ray examination revealed a Kelly clamp lodged in the upper right quadrant of her abdomen. At the trial the plaintiff called the hospital superintendent and the three physicians to testify under the law permitting a party to call and examine an adverse party. She produced no medical expert of her own, however.

Lacy, the physician in charge of the operation, testified that he scheduled the operation after deciding that an exploratory examination of the upper right quadrant of the plaintiff's abdomen should be made. Lacy and Slegal, who was assisting, made an incision from plaintiff's naval upward, exposing her gallbladder. Lacy called in Eiskamp who, after visual examination, recommended that the gallbladder be removed. After Eiskamp left, Lacy and Slegal discovered a "mass" in the sigmoid colon which appeared to be cancerous. Eiskamp was again called in, he agreed that the mass should be removed and offered to help. They decided not to operate on the gallbladder, and, while Lacy began to close the upper half of the incision, Eiskamp and Slegal removed the mass from the lower left quadrant. Eiskamp performed no work in the upper portion of the abdomen and he left before final closure of the incision. Lacy and Slegal used Kelly clamps in the operation but Eiskamp did not. Lacy testified that he did not request the surgical nurse to make an instrument count. Slegal's testimony substantially confirmed that of Lacy.

Eiskamp testified that he used no Kelly clamps, did not take part in closing the upper part of the incision and left before final closure of the abdomen.

The hospital superintendent testified that surgical instruments are furnished by the hospital and that hospitals in the area "have no established practice of instrument counting either before or after surgery." She said, however, that sponges and needles are usually counted and an instrument count is made if requested by the surgeon.

When a foreign object is left in a patient's abdomen, said the Supreme Court, it is ordinarily the result of the negligence of someone. Such evidence is sufficient, said the court, to raise an inference of negligence under the doctrine of *res ipsa loquitur* and, where a patient receives unusual injuries while unconscious, all persons who had any control over his body or the instrumentalities which might have caused the injuries may properly be called upon to meet the inference of negligence by explaining their conduct.

The plaintiff contended that the inference of *res ipsa loquitur* was not dispelled in this case. She contended that testimony given by defendants as adverse witnesses cannot be used to dispel the inference of *res ipsa loquitur* on which she relied.

Section 2055, said the court, provides in effect that a party to a civil action may be examined as if under cross examination by the adverse party and that the party examining such witness shall not be bound by the witness' testimony and may rebut it by other evidence. Such testimony, however, is evidence in the case and the provision that a party calling an adverse witness shall not be bound by his testimony does not mean that such testimony may not be given its proper weight. The provision merely means that the party calling such witness is not barred from rebutting his testimony or impeaching him. It may therefore be used to dispel an inference on which the plaintiff relies, provided the evidence is clear, positive, uncontradicted, and of such a nature that it cannot rationally be disbelieved. There are situations, continued the court, where the interest of a party in obtaining a judgment favorable to himself will not render all his testimony subject to disbelief. For example, where part of a defendant's testimony is harmful to him but favorable to a co-defendant, that part may be used to rebut an inference unfavorable to the co-defendant provided there is nothing to indicate collusion or any other reason for disbelieving the testimony. The clear and uncontradicted testimony of the three physicians as to Eiskamp's participation in the operation was to the effect that Eiskamp was not responsible for leaving the clamp in the plaintiff's abdomen. The testimony of Lacy and Slegal was disadvantageous to them because the exoneration of one defendant would increase the possibility of liability on the part of the other defendants. There is no rational ground for disbelieving their testimony. The court therefore concluded that the inference against Eiskamp under the doctrine of *res ipsa loquitur* was, therefore dispelled as a matter of law.

The testimony relied on to dispel the inference of negligence as to the hospital and the surgical nurse, however, was that of the hospital superintendent. As an employee of the hospital, she obviously had an interest in the outcome of the case and her testimony could, therefore, be disbelieved by the trier of fact. Even if the trier of fact accepted the testimony as true, it is not of the character required to dispel the inference of negligence raised against the hospital and the nurse. She testified that there was no established practice of counting instruments, other than sponges and needles, before or after surgery. Proof of practice or custom is some evidence of what constitutes due care but it does not conclusively establish the standard of care. It cannot be said as a matter of law that there was no duty on the part of the hospital and the nurse to keep an instrument count. Accordingly, the judgment of the lower court in favor of the defendant physician was affirmed and the judgment in favor of the hospital and the surgical nurse was reversed *Leonard v Watsonville Community Hospital, 305 P (2d) 36 (Calif, 1956)*

Paternity Conclusive Effect of Blood Grouping Tests —The defendant was charged with fornication and bastardy and from a conviction appealed to the superior court of Pennsylvania

A pathologist testified on behalf of the defendant that blood grouping tests which he had made excluded the defendant as the father The defendant contended that, because of this testimony, there should have been a directed verdict of not guilty Section 306 of 28 Pennsylvania Statutes provides In any proceeding to establish paternity, the court, on motion of the defendant, shall order the mother, her child, and the defendant to submit to one or more blood grouping tests by a duly qualified physician to determine whether or not the defendant can be excluded as being the father of the child, and the results of such tests may be received in evidence but only in cases where definite exclusion of the defendant is established ' The court said that this statute does not accord to blood grouping tests the conclusive effect contended for by the defendant It merely provides that such test may be received in evidence It is, therefore, clear that the trial judge's refusal to direct a verdict of not guilty was not erroneous On other grounds, however, the judgment of the lower court was reversed and a new trial ordered *Commonwealth v Hunscik, 128 A (2d) 169 (Pa, 1956)*

Malpractice Action Barred by Release of Joint Tort-feasor —This was an action for damages for injuries allegedly caused by the malpractice of the defendant physicians From the granting of the defendants' motion for judgment on the pleadings, the plaintiff appealed to the court of appeals of Lorain County, Ohio

The malpractice allegedly occurred during the defendants treatment of injuries received while attempting to board a bus operated by the city The defendants pleaded a release given by the plaintiff to the city in settlement of her case against the city for the injuries received as a result of the negligent operation of its bus The release, which by its terms relinquished all right to recover from the original tort-feasor, the city, said the court, operates as a bar to recovery against a physician subsequently retained for negligent treatment of the original injuries The bar which prohibits a second claim predicated on malpractice is based upon the theory that the original tort-feasor is liable for the plaintiff s injuries, including the aggravation thereof at the hands of a physician selected with reasonable care by the injured person Therefore, when settlement is made with the one liable for the total damages, including the aggravation, full compensation has been received for all injuries arising out of the accident The judgment of the lower court in favor of the defendant physicians was accordingly affirmed *Knight v Strong, 140 N E (2d) 9 (Ohio, 1955)*

Malpractice Application of Res Ipsa Loquitur to Gastroscopic Examination —This was an action against the defendant physician for damages alleged to have resulted from the negligent puncturing of the plaintiff's esophagus during a gastroscopic examination for cancer made by the defendant physician From a judgment in favor of the defendant, the plaintiff appealed to the Supreme Court of Pennsylvania

The plaintiff, a woman of 45, entered a hospital, at which the defendant physician was head of the division of gastroenterology, for the purpose of undergoing a gastroscopic examination for the detection of cancer She received medication in the form of Demerol and a hypodermic injection of atropine sulfate, and a gastroscope was inserted into her esophagus No resistance was encountered until the gastroscope reached the cardia, or esophageal orifice, at which place there was an obstruction apparently due to spasm Gentle pressure and insufflation aimed to distend the walls of the stomach so as to clear the passage for the tube were applied but the plaintiff commenced to show signs of distress and an emphysema of the upper abdomen, neck, and cheek occurred The tube was immediately removed and the plaintiff was taken to the surgical ward, where it was discovered that there was a puncture of the esophagus about 1 25 in in size which required a thoracotomy for the removal of a rib and the suturing of the puncture The plaintiff produced no evidence in addition to her own testimony and the cross examination of the defendant, and the trial court therefore entered a nonsuit because of the plaintiff's failure to introduce medical testimony tending to prove that the defendant had acted in any way contrary to the standard medical practice

On appeal, the plaintiff contended that the jury could infer negligence from the mere occurrence of the puncture and from the fact that the gastroscope was under the exclusive control of the defendant In other words, the plaintiff argued that the doctrine of res ipsa loquitur should be applied

The Supreme Court said that no presumption or inference of negligence arises merely because the medical care or surgical operation terminated in an unfortunate result which might have occurred even though proper care and skill had been exercised, and where the common knowledge or experience of laymen is not sufficient to warrant their passing of judgment The only exception to this otherwise invariable rule, said the court, is in cases where the matter under investigation is so simple, and the lack of skill or want of care so obvious, as to be within the range of the ordinary experience and comprehension of even nonprofessional persons Since expert testimony is necessary to establish negligent practice in any profession, the plaintiff's suit must fail in the absence of evidence that the defendant s conduct was not in accord with the ordinary and approved procedure of gastroenterologists engaged in such specialized practice No such evidence was presented

Accordingly the Supreme Court of Pennsylvania affirmed the action of the trial court in favor of the defendant physician *Robinson v Wirts, 127 A 2d 706 (Pennsylvania, 1956)*

Malpractice Release of Joint Tort-feasor as Bar to Action Against Physician —This was an action for damages caused by the alleged negligence of the defendant physician From a summary judgment in favor of the defendant, the plaintiff appealed to the court of civil appeals of Texas

The plaintiff, having been injured in an automobile accident, selected the defendant as his physician. Subsequently, the plaintiff sued the third party tort-feasor for damages caused by the accident and a little later he sued the defendant for damages caused by alleged malpractice in the treatment of the injuries resulting from the accident. While both suits were pending, the plaintiff settled his claim against the tort-feasor, dismissed his suit against him, and executed a common-law release. This release, said the court, operated to fully and finally discharge the tort-feasor. Furthermore, continued the court, it operated to bar any further action by the plaintiff against the defendant physician.

The plaintiff contended that the fact that the tort-feasor had only $5,000 worth of liability insurance, and the fact that his injuries were worth much more than that amount, was ample evidence of his intent not to settle his entire cause of action when he executed the release. The court said that it could not consider the plaintiff's reasons for doing what he did pursuant to the negotiation of the settlement, nor the financial responsibility of the person with whom he settled. This might have been done in connection with litigation between the plaintiff and the tort-feasor, but not in connection with litigation between the plaintiff and the defendant physician. Accordingly, the summary judgment of the lower court in favor of the defendant physician was affirmed. *Sims v. Aurinuger, 301 S.W. (2d) 286 (Texas, 1957).*

MISCELLANY

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES

J. Murray Kinsman, M.D.

This statement is appearing in the August issue of the Federation Bulletin.—Ed.

The lack of an effective means of evaluating the professional (and other) qualifications of graduates of foreign medical schools has plagued state boards and hospitals for years. Beginning in 1950, the Council on Medical Education and Hospitals in collaboration with the Association of American Medical Colleges began to maintain a listing of some 50 foreign medical schools whose graduates were theoretically to be considered comparable to the graduates of our own schools.

For many reasons this proved to be quite unsatisfactory from the standpoint of determining the qualifications of the individual graduate. To consider the possibility of devising other ways of measuring that factor, in 1954 the Federation [of State Medical Boards of the United States] joined with the American Hospital Association, the American Medical Association, and the Association of American Medical Colleges to form what was called "The Cooperating Committee on Graduates of Foreign Medical Schools." After many months of deliberations, the committee finally evolved a plan which was designed to evaluate the individual foreign graduate rather than his school. The plan was scrutinized carefully and approved by legal counsel before being presented to the parent organizations; in due time each of the four approved it in principle.

The proposed program and background information was published in some detail in the September, 1956, issue of the *[Federation] Bulletin*. As a result of the approval of the committee's recommendations, the Evaluation Service for Foreign Medical Graduates was organized and incorporated under the laws of the state of Illinois on May 14, 1956. The Cooperating Committee had made very careful estimates of the financial probabilities and had estimated that the program should be self-supporting after about two years of operation but that it would need substantial aid until that time. Between them, the four parent organizations pledged grants totaling $25,000, in order to defray expenses in connection with getting the organizational setup under way, but the additional funds needed to maintain operations during this interim period were to be sought from grants. On June 1, 1956, one foundation announced that it would make a grant of $100,000, contingent upon this being matched from some other source.

Other foundations were approached immediately and it was quickly discovered that it was unlikely that the matching grant could be obtained until the organization was declared tax-exempt. Efforts in this direction were begun at once, with the help and advice of legal counsel which the Evaluation Service had employed. It was discovered that, in order to acquire tax-exempt status, two changes would be desirable: (1) to emphasize the educational aspects of the program by changing the name and the statement of purposes of the organization, and (2) to indicate the public service aspects of the program by adding to its Board of Directors at least two members representing governmental or quasi-governmental agencies. Consequently, on Dec. 14, 1956, the name of the organization was changed to the "Educational Council for Foreign Medical Graduates," and the Board was enlarged from the 8 members representing the four parent organizations, to 10, the additional two being trustees-at-large and representing the State Department, and/or the Department of Health, Education, and Welfare, and/or the Department of Defense. As it turned out, the State Department is not legally permitted to participate in this type of organization, so the two trustees-at-large were selected from nominees proposed by the other two.

On Feb. 14, 1957, the Educational Council was given 'tentative' tax-exempt status (unqualified tax-exemption cannot be given until the program has been in actual operation for one year).

On April 4, 1957, financial support for the first two years of operation was assured when a second foundation awarded the grant matching that of the first one, to be effective when a director was employed.

A paid director was then sought. This required a much longer time than had been anticipated. At last he was found in Dr. Dean F. Smiley, now secretary of the Association of American Medical Colleges who, on

---

Chairman, Board of Directors, Educational Council for Foreign Medical Graduates.

July 9, 1957, was offered the position and accepted it In order to fulfill his commitments to the Association he went on a part-time basis beginning July 15, 1957, and will become full time on or about Oct 1

The effective date of implementation of the program of the Educational Council for Foreign Medical Graduates is therefore July 15, 1957 Its headquarters will presumably be in Evanston—this has not been definitely decided at the time of this writing Until the staff has been assembled it is not desired that much publicity be given in order to avoid being deluged with inquiries and problems prematurely Once the staff has been assembled it is planned to seek the most widespread publicity, particularly in foreign countries

It should be emphasized that the Educational Council is not concerned with the placement of individual foreign physicians in hospitals nor with assisting individuals to obtain licenses to practice Its function is primarily to evaluate individual foreign graduates and to supply information concerning this evaluation to state boards, hospitals, or other agencies upon legitimate request At the same time, in compliance with its stated purposes, it will have a responsibility to promote the opportunity to further their medical education in this country of those foreign graduates who can benefit the most from it It is not its purpose to "keep the foreign graduate out , on the contrary it hopes that its program will result in a hospital knowing in advance of his coming more about a foreign doctor who applies for an internship or residency, and in providing state boards with more valuable information about those who apply to it for examination for licensure than they can obtain at present

AMERICAN MEDICINE ABROAD—HONG KONG

Lou Hazam

This is the second of a series of on-the-scene reports from the ' March of Medicine" production team, which is traveling around the world to film an hour-long television program on the work of American doctors abroad—the services they perform, the conditions they face, the personal satisfaction they receive in their unofficial roles as America's medical diplomats The author, Mr Lou Hazam, has written all but one of the "March of Medicine" scripts since the series started in 1952 In this article, he tells of the dedicated work of Dr Olaf K Skinsnes in Hong Kong Also, on the "March of Medicine" itinerary are such places as Korea, Sarawak, Burma, Nepal, India, Ethiopia, Lebanon, Turkey, and Guatemala The program, sponsored and produced by Smith, Kline & French Laboratories in cooperation with the American Medical Association, will be seen in color next spring over the NBC television network —Ed

Every Friday morning, in the British Crown Colony of Hong Kong, a former mine layer, the Ling Hong, emerges from amidst the hill city's fantastic floating population—200,000 living on sampans and junks—and heads out into the bay Aboard is a graduate of the University of Chicago Medical School, Dr Olaf K Skinsnes, one of the many American doctors who are serving in a wide variety of capacities overseas In an hour and 10 minutes he will reach his goal It is a leper island known as Hay Ling Chau—the Isle of Happy Healing—the result of a cooperative effort that is testament, in part, to his concern and affection for the Chinese people among whom he lives and works

Dr Skinsnes was born in China, the son of medical missionary parents He grew up and went to school there until the time arrived to go away to college He came to the States and completed his undergraduate work at the University of Minnesota and St Olaf College, Minn After interning at New York Hospital-Cornell Medical Center and being certified a diplomat of the American Board of Pathology, he married and in 1949 left with a family that now includes two small daughters and set out to serve, as his Lutheran father before him, as a medical missionary to China

Dr Skinsnes knew he was taking a calculated chance, what with the political changes then evident there, but he sincerely believed it was a chance worth taking He had but to arrive in Hong Kong to see for himself the great exodus of missionaries from China and to conclude that foreigners would no longer be tolerated in the country he had known as home ever since he was a boy

Invited to join the department of pathology at the University of Hong Kong, Dr Skinsnes settled down with his family in a home on the university grounds high on a hill overlooking what is perhaps one of the world s most beautiful commercial ports He became the only foreign member of an otherwise all Chinese department of this British university, and for some time the only American on its staff It was here that the "March of Medicine' crew found Dr Skinsnes and heard this tale we tell you now

Leprosy is perhaps the Orient's most feared disease Ever since ancient times, surrounded by ignorance and superstition, it has been dreaded—believed by many to be venereal, inheritable, and a punishment for evil sent by the gods One had but to contact it to bring upon himself disgrace, banishment from his neighbors and community, and often a fate that was even worse As for any hope, there is a Chinese saying that goes 'If leprosy can be cured, salted fish can live again!"

All kinds of beliefs took hold One had it that lepers ate the hearts of newborn infants in an attempt to get well Despised, forsaken, some have been known to choose suicide as the only way out Indeed there is one well-authenticated story that is comparatively recent of a community gathering all its lepers into a boat and taking it far out to sea and burning it, taking care to drown those who sought to swim to safety

Dr Skinsnes was interested in leprosy as a research problem, with a view to seeking a better understanding of the disease that might result in more efficient ways of treatment and eradication Inquiry brought out that none believed that there was much of a leprosy problem in Hong Kong It took only a little investigation to reveal that the problem was actually extensive Seeking and securing a grant from the American Leprosy Missions, he made further studies of leprosy incidence and distribution, and began investigations concerning the pathology of the disease and the social reactions to it In time, he joined forces with Dr Neil Fraser of the British Mission to Lepers to bring the matter to the attention of the Hong Kong community Once the community was apprised of the facts, it became truly aroused to do something about it A local organization was formed to combat leprosy, and widespread support was given to its efforts by many leading Chinese and British citizens All of this ultimately resulted in moving a colony of lepers that had been established in matsheds on a stony beachhead not far from the city to the island of Hay Ling Chau

We could see that this island, as we approached it, was flanked by other, smaller islands

'What's that one over there?' we inquired

'Communist,' he replied It seemed too close for comfort "It wouldn't pay to have to put in there'

Hay Ling Chau itself is hilly, covered by evergreen trees and shrubs and rising from the sea to a pointed pinnacle Here, where once there was nothing, are now a hospital, a building for patients with both leprosy and tuberculosis, dormitories for housing the patients, a church, a school, woodworking shops, livestock, and fields of vegetables A permanent staff resides on the island, including Dr Fraser and two medical officers—Dr Douglas Harman and Dr Wong—caring for over 500 patients, who raise their own food supply Complete with laboratory facilities for study, it is in every sense a modern leprosary

The original research project has continued and provided a considerable portion of the information and stimulus needed for the center s development Besides serving as a treatment and research center, it serves also as a teaching center to which final-year students of the University of Hong Kong Medical School come for at least a week of training to further familiarize themselves with the disease In addition, today outpatient clinics in Hong Kong care for about 1,500 outpatients a day in the Hong Kong area itself

Thus, those who had no hope before now take hope and are helped—many of them—to return to a normal useful life in the community

It is for this reason that the Smith, Kline & French medical television unit filmed scenes on the Isle of Happy Healing For it is another splendid and graphic example of the contribution American doctors are making all over the world

MEDICAL FILM REVIEWS

Aneurysms of Abdominal Aorta Surgical Considerations Based upon Analysis of 350 Selected Cases 16 mm, color sound, showing time 25 minutes Prepared by Michael E DeBakey M D Denton A Cooley, M D, and E Stanley Crawford, M D, Houston, Texas Produced in 1957 and procurable on loan from Michael E DeBakey, M D Baylor University, Texas Medical Center, Houston

This film deals largely with the technical aspects of resection of the abdominal aorta for aneurysm and its replacement by various types of grafts At the outset, there is a brief presentation of the physical diagnosis of abdominal aneurysm and the x-ray features of its diagnosis, in particular, the infrequent need for aortography is pointed out The major part of the time is spent in showing the important parts of four abdominal aorta aneurysm resections A different kind of replacement is used in each instance showing a reconstituted homologous aortic bifurcation, a woven crimped nylon bifurcation of the Edwards Tapp variety, a woven nylon bifurcation of the Sanger type, and, finally, a crimped dacron bifurcation developed by DeBakey and his co-workers The material is extremely well presented, both from a technical and photographic standpoint and from the standpoint of the selection of the steps of operation which will be of interest to the observer Quite properly, the author does not offer any final comparison as to the value of the various grafts and prostheses used, because it is too early to have a reliable opinion in this direction In every case, the technical result observed was excellent and every point in technique was clearly made The narration is clear and unhurried This film can be highly recommended for almost every type of medical audience Its interest to students should lie in the points concerning diagnosis and in the frequent mention which is made to the pathology To specialists in general practice, its value should be in pointing out the fact that abdominal aortic aneurysms are dangerous lesions, that their danger is not one over a period of great length but rather over a brief period of months or a few years, and, further, that resection with a very acceptable mortality rate is available for these patients The value to surgeons and particularly to those surgeons interested in cardiovascular work lies in the clear presentation of the technique which has been developed at one of the most active centers in the country

Human Heredity 16 mm color sound showing time 22 minutes Sponsored by the E C Brown Trust, Portland Ore Produced in 1956 by Churchill Wexler Film Productions Los Angeles Procurable on loan (service charge $3) from Motion Picture Library American Medical Association 535 North Dearborn St Chicago 10

This outstanding film presents the facts concerning human heredity, sex roles and determination, and the influence of environment on behavior and attitudes It contributes to the full understanding of important social changes of our times and to the separation of fact from superstition The picture shows how it is possible to handle subjects, once considered delicate and embarrassing, in the most inspiring and delightful manner The discussion of the predetermination of sex is important and well handled, and the influence of environment on appearance and behavior after heredity has made its contribution is well brought out The technical detail is as accurate as it can be in order to be manageable as an elementary introduction to an extremely complicated subject The narration deserves special praise because it is well planned, perfectly intelligible throughout, and delivered slowly enough for everyone to follow The animation is superior and the photography is excellent The film is ideally suited for ninth grade general science and high school biology courses and for physicians who are called to address adult groups such as service clubs and parent teacher associations

An Aid to Therapy (Bacterial Antibiotic Susceptibility Testing) 16 mm, color sound showing time 25 minutes Prepared by Leo L Leveridge M D, and Frederick C Fink, Ph D, Brooklyn, N Y Produced in 1957 by Campus Films, New York, for and procurable on loan from Pfizer Laboratories, Chas Pfizer & Co, Inc, 630 Flushing Ave Brooklyn 6, N Y

The purpose of this film is to acquaint the physician with the advantages and limitations of the commonly available methods of bacterial antibiotic susceptibility testing, so he can better evaluate the reports furnished him by the laboratory It is designed primarily for the physician to whom bacterial antibiotic susceptibility testing is new and is intended to give some familiarity with the common methods, so that the physician can make the optimal use of this aid to therapy with antibiotics For this purpose, the film is highly satisfactory It gives a good general description, in not too technical a fashion, of the commonly accepted techniques It should also be useful for medical students and for students of medical technology The film discusses clearly the nonquantitative interpretation of the disk method and the difficulties of accurate standardization It would have been useful to point out the lamentable lack of uniformity between the different commercially available sensitivity disks The film can be recommended for the audience for which it was intended

Brachial Plexus Block 16 mm, color, sound, showing time 20 minutes Prepared in 1955, by and procurable on loan from Charles C Wycoff, M D, San Francisco Hospital, 22nd and Potrero Sts, San Francisco 10

This film presents the author's technique for brachial plexus block using as landmarks the line of transverse processes, angle of first rib, and scalene cleft and using occlusion of radial pulse by pressure on the subclavian artery at the first rib The area of anesthesia and the signs of anesthesia are also shown This film should be subtitled "Anatomy and Technique of the Brachial Plexus Block" It does not give indications, contraindications, or complications, nor does it go into the anesthetic agents that might be used, rather, with really an inadequate amount of information, it recommends lidocaine (Xylocaine) hydrochloride One would have hoped that the complications could have been listed, and it would have been so easy to have listed them on an anatomic basis that the omission is rather strongly apparent This is a good film from the standpoint of the anatomic rules and is recommended for showing to anesthesiologists

Transvaginal Pelvioscopy "Culdoscopy' 16 mm, color, sound, showing time 25 minutes Prepared by A R Abarbanel M D, Los Angeles Produced in 1956 by Aren-Schon Medical Productions, Los Angeles Procurable on rental ($12 50) or purchase ($225) from A R Abarbanel, M D 6333 Wilshire Blvd, Los Angeles 48

This film demonstrates in detail the author's technique for pelvioscopy which is performed as an office or outpatient procedure Indications, contraindications, and complications are illustrated Various phases of ovarian physiology, including the ovulatory process, the syndrome of ovarian polycystosis, the peritoneal factor in infertility, and findings in secondary amenorrhea are demonstrated by animation and drawings Although this is a simplified procedure in the hands of the author, it is more difficult for the uninitiated, and the accidents which may occur in the cul de sac should be pointed out The photography and technical details of the film are above average It describes, however, a highly technical procedure and is recommended for gynecologists who are interested in this particular field

Vaginal Hysterectomy for Fibroids 16 mm, color, sound, showing time 11 minutes Prepared by Frederick J Hofmeister, M D, Leo R Grinney, M D, Hollis A Paegel, M D, and R C Brown, M D, Milwaukee Produced in 1951 and revised in 1957 Procurable on loan from Ohio Chemical and Surgical Equipment Co, 1400 E Washington Ave, Madison, Wis

The purpose of this film is to demonstrate the Heaney technique of vaginal hysterectomy It shows an operation for uterine fibroids greater in size than a three-month fetus Morcellation technique is shown as well as the technique of removing a tube and ovary vaginally In this case, no repair was necessary The film portrays admirably the operation of vaginal hysterectomy with morcellation of a fibroid nodule The sound is good and the photography is fair The film is recommended to anyone who wishes to observe in some detail the various steps in removing a uterus with myomas

Vaginal Hysterectomy with Repair of Prolapse Demonstrating Heaney Technique with Modification 16 mm, color, sound, showing time 17 minutes Prepared by Frederick J Hofmeister, M D, Leo R Grinney, M D, Hollis A Paegel M D, and R C Brown, M D, Milwaukee Produced in 1951 and revised in 1957 Procurable on loan from Ohio Chemical and Surgical Equipment Company, 1400 E Washington Ave, Madison Wis

In this film, a vaginal hysterectomy demonstrating the Heaney technique is performed on a patient who has a third degree prolapse All the steps used in doing a vaginal hysterectomy are indicated The cystocele and urethrocele are repaired and a posterior colpoperineorrhaphy is performed In general, this is an excellent film, however, there is no mention of the enterocele and there is not enough emphasis on its correction The term "corner sutures' should be more clearly demonstrated This film will be of interest to specialists in training and general practitioners

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Insulin Deficiency and Diabetes F Gerritzen, E L Noach, M van Wijhe and L E M Valk Acta endocrinol 25 91-100 (May) 1957 [Copenhagen]

An intensive search in the literature does not provide convincing experimental or clinical evidence that the late complications of diabetes mellitus are caused by insulin deficiency There remains the question whether the whole clinical picture of diabetes mellitus is accounted for by insulin deficiency only or whether insulin deficiency is only a part of the clinical syndrome of diabetes In an attempt to find out whether it is possible to demonstrate the occurrence of late diabetic complications in the course of experimental insulin deficiency, rats were made deficient in alloxan insulin for 1 year They were injected subcutaneously with a single dose of 75 mg of alloxan (in aqueous solution) per kilogram of body weight All animals showed a glucosuria during the first week after alloxan treatment Of 8 animals which survived the entire experimental period, 5 had a permanent glucosuria (insulin-deficient rats) and 3 never again had a positive glucose reaction in their urine and served as controls It was not possible to observe any changes in the livers, kidneys, eyes, and larger and smaller vessels of these animals comparable to those observed in man with diabetes mellitus This study therefore gives no support to the general and commonly accepted concept, that, at least in the rat, insulin deficiency is responsible for the occurrence of late diabetic complications

Hereditary Pancreatitis Report on Two Additional Families J B Gross and M W Comfort Gastroenterology 32 829-854 (May) 1957 [Baltimore]

The authors cite earlier reports on a familial form of chronic relapsing pancreatitis and present the pedigrees of 2 additional, unrelated families, in which the hereditary form of chronic relapsing pancreatitis and sequelae occurred These additional observations tend to confirm the original impression that in certain families chronic relapsing pancreatitis is transmitted as an autosomal dominant gene The hereditary form of the disease appears to resemble the sporadic form in most respects, except that the hereditary form does appear to begin earlier in life and appears so far to involve females predominantly, whereas males seem more often affected in the usual form of chronic pancreatitis The cause and pathogenesis of the disease are not known Alcohol and hyperlipemia appear to be unimportant factors in the etiology of the hereditary form of the disease, nor have gallstones been associated It is suspected that the inherited defect predisposing to recurring bouts of pancreatitis and sequelae is metabolic in nature It appears quite probable that the hereditary form of chronic relapsing pancreatitis occurs more frequently than has been realized in the past and that increasing awareness of the entity will result in the discovery of many more families so affected

Symptomatology in Ulcer Disease Clinical Evaluation of Symptoms and Examination of Gastric Function in 512 Cases Treated Medically O L Olesen Ugesk læger 119 407-417 (April 4) 1957 (In Danish) [Copenhagen]

The 512 cases studied were predominantly chronic Ordinary clinical methods do not allow certain distinction between different forms of ulcer disease when the usual roentgenologic criteria are applied as the introductory basis Ulcer dyspepsia without roentgenologic changes, gastroduodenitis, and duodenal ulcer show marked points of similarity both in history and clinically and will naturally be interpreted as different phases of the same picture, dyspepsia without roentgenologic changes representing the earliest and mildest stage of the disease, which calls for hospital treatment This group shows a slightly lower average age than the other groups, somewhat shorter average duration, somewhat weaker symptoms, and, like the gastroduodenitis group, slightly lower average acidity than those with duodenal ulcer but the same frequency of hypersecretion The more severe symptoms in persons with verified ulcer are explained by increasing anatomic changes In ulcer of the corpus of the stomach there are marked deviations from the other groups in only a few points but smaller deviations in many points Different relations of heredity, higher average age, tendency of the general condition to be more affected, the disproportionate preponderance of older patients in cases of bleeding ulcer, the 2 deaths in the group, lack of hyperacidity—all these conditions indicate that ulcer of the corpus is subject to different laws than other types of ulcer and develops independently of the hyperacidity that in some way plays a part in the pathogenesis of gastroduodenal and duodenal ulcer The assumption is supported that dyspepsia of so called ulcer type, the roentgenologic-clinical picture of gastroduodenitis, duodenal ulcer with a definite niche, and a duodenal ulcer made probable by roentgenologically demonstrable bulbus

The place of publication of the periodicals appears in brackets preceding each abstract

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals Requests for periodicals should be addressed Library, American Medical Association Periodical files cover 1948 to date only, and no photoduplication services are available No charge is made to members, but the fee for others is 15 cents in stamps for each item Only three periodicals may be borrowed at one time, and they must not be kept longer than five days Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them deformity represent different forms of the same basic disease Ulcer of the corpus must be regarded as a disease not connected with gastroduodenitis Until other proof is forthcoming the corpus ulcer must be regarded as a far more serious illness than duodenal ulcer Surgical treatment must be considered as soon as the ulcer is recognized

Treatment of Gangrene of the Feet and Legs by Walking W T Foley Circulation 15 689-700 (May) 1957 [New York]

The success of exercise by using a walking cast in the treatment of fractures suggested that walking might prove helpful in the treatment of gangrene of the feet and legs The first patient in whom exercise was used for gangrene was a young truck driver who had thrombophlebitis obliterans and a gangrenous right first toe After a week s hospital stay he was allowed to walk about on crutches Prompt relief of his intense pain resulted, which was so gratifying that he was then permitted to bear partial weight and walk with a cane Instead of retarding the healing, it took place with unexpected rapidity The feared spread of infection did not occur This favorable experience led to the adoption of walking in 21 other patients At first walking was permitted only in patients with sharply localized gangrene, but as experience increased it was permitted in more recently developed gangrene If the toes are involved, the patient is encouraged to hobble on the heel If that too is involved, the foot is bandaged and weight bearing is distributed over the entire foot

The treatment failed in only 1 of the 22 patients This woman had improved during her hospital stay, but when she returned home her family refused to allow her to walk because of her gangrenous toes Atrophy and spreading infection developed, requiring amputation of the leg Success in the treatment of 21 patients suggests that walking should be added to the medical regimen of oscillating bed, reflex heat, abstinence from tobacco, antimicrobial ointments, bandages, the release of vasospasm, and the treatment of associated conditions, such as diabetes and cardiac decompensation Ambulation results in a decreased need for nursing care Patients are able to walk to the bathroom and attend to their personal needs They are able to leave the hospital sooner While at home they are also less of a burden Many are able to return to work while still under treatment

The Present Status of Philippine Hemorrhagic Fever R M Guerrero Santo Tomas J Med 12 1-7 (Jan-Feb) 1957 [Manila]

There has been much discussion as to whether Philippine hemorrhagic fever is a new disease or an old disease with a new physiognomy The author believes that it is a new disease at least as far as the present generation of physicians is concerned Several types of hemorrhagic fever have been described in the last 20 years in regions of Manchuria and Siberia and also in Bukovina, Crimea, Uzbeskistan, Omsk, and north Scandinavia Lately the Korean or Far Eastern type was described by American authors All of these forms seem to have a nonbacterial etiology, whether viral or rickettsial is not yet definitely known In several forms the disease is transmitted through the bite of an insect and the reservoir of the infection is found in cattle, horses, and ticks The best known type is the Korean type because it was studied by American research workers during the epidemics of 1951-1953, in which several thousand cases were observed It has been suggested that the Philippine type of hemorrhagic fever might be the Korean form brought here by the Filipino troops who fought in Korea

The disease begins abruptly after an unknown incubation period The first or febrile stage lasts 2 to 6 days and is characterized by fever with chills or convulsions, headache, nausea vomiting, flushed face, and injected eyes The second is the hemorrhagic stage, which is usually preceded by abdominal pain and tenderness The hemorrhages take the form of hematemesis, melena, or petechial hemorrhages This stage may begin while the fever is up or after the fever has gone down During this stage there is a tendency to hypotension, which may lead to shock, sometimes irreversible This is the cause of the fatalities This stage lasts 1 or 2 days only and is followed by a prompt recovery The laboratory findings include a positive tourniquet test, normal leukocyte count, a high stab count, monocytosis, and plasmacytosis Blood platelets are often diminished or absent, and the retractility of the clot is diminished The management consists principally in careful nursing, maintenance of nutrition and hydration, and watchfulness with regard to the change in pulse and blood pressure Prompt treatment of the hypotension by means of blood transfusion, polyvynilpyrrholidone, and levophed have given the best results Substances intended to diminish capillary fragility have been used without conclusive results Antibiotics and cortisone have not been shown to be of real value

Wilson's Disease, an Inborn Error of Metabolism with Multiple Manifestations A G Bearn, Am J Med 22 747-757 (May) 1957 [New York]

Classification of Wilson's disease (hepatolenticular degeneration) as an inborn error of metabolism is supported by a large amount of evidence concerning the hereditary and biochemical aspects of the disease in 26 patients studied by the author and in additional patients reported by other workers The clinical manifestations of Wilson's disease usually arise during adolescence, and most of the patients are between the ages of 12 and 20 years They fell into 2 broad and overlapping clinical categories In one, the symptoms were predominantly referable to the nervous system, and in the other, the disease appeared restricted to symptoms and signs of hepatic cirrhosis The neurological form of the disease was most frequently observed, symptoms of tremor, rigidity, dysarthria, and dysphagia stem from disorganization of the lenticular region of the brain

The primary inherited defect appears to involve copper metabolism and is characterized by defective synthesis of serum ceruloplasmin, a low serum copper level, and an increased quantity of albumin-bound (direct-reacting) copper in the serum An increased accumulation of copper in the liver, brain, and other tissues occurs The excretion of copper in the urine is excessive The effect of estrogens on the serum ceruloplasmin concentration was studied in 7 patients who were given ethynil estradiol (Estinyl) and diethylstilbestrol for periods up to 5 weeks In 3 patients, in whom the serum ceruloplasmin level was the least depressed, administration of estrogens resulted in a rise in the ceruloplasmin levels to normal or greater than normal values, in 1 additional patient a slight rise was observed In the remaining 3 patients no significant change in the ceruloplasmin level was demonstrable Accumulation of copper in the kidney in Wilson's disease results in a characteristic renal lesion, similar in many respects to that seen in the Fanconi syndrome Glycosuria, aminoaciduria, phosphaturia, and uricosuria may occur An alteration in renal hemodynamics is usually demonstrable Radiographic examination of the bones and joints was made in 19 patients and revealed abnormalities in 13 Severe osteoarthritis and bone fragmentation were common More rarely, osteomalacia and spontaneous fractures were also seen

The severity of the disease does not appear to be related to the depression of the serum ceruloplasmin level, and restitution of the serum ceruloplasmin level to normal, either by infusion of the purified protein or by the administration of estrogens, has not led to any clinical improvement The improvement which may occasionally follow the use of 2,3-dimercaptopropanol (BAL) and other chelating agents is not well correlated with the magnitude of the increased copper excretion The reason why the lesion is confined to the liver in some patients and to the brain in others cannot be easily explained on the current hypothesis that the primary effect of the abnormal gene, when present in homozygous form, is to diminish the normal synthesis of serum ceruloplasmin and, possibly, other related proteins This difference in the location of the lesion could be due to environmental causes or, more probably, to genetic influences still unassessed

Agammaglobulinemia with Splenomegaly K M Citron Brit M J 1 1148-1151 (May 18) 1957 [London]

The author reports 2 cases of agammaglobulinemia with splenomegaly in a 33-year-old man and in a 17-year-old woman The 2 patients had the features of the acquired idiopathic type of agammaglobulinemia They were in good health before the onset of symptoms of recurrent infection and they did not have any primary disorder to which the development of agammaglobulinemia might have been attributed The normal zinc-flocculation, thymol-turbidity, and total globulin levels, which were determined in the man in the early stages of the disease, provided strong circumstantial evidence that gamma globulin was present in appreciable amounts at the first time these tests were made, so that the agammaglobulinemia must have developed later Gross increase in the size of the spleen was a striking clinical feature in both patients In the woman, the increase in the size of the spleen was present before severe infections had occurred and the spleen was observed to increase in size during the next 3 years until splenectomy was performed In the man, increase in the size of the spleen was noted 8 years after the onset of the disease, with symptoms of infection and enlarged lymph nodes, and the spleen increased in size over the next 6 years The liver was enlarged in both patients Generalized enlargement of lymph nodes occurred in both patients, including the hilar lymph nodes in the man and the intra-abdominal lymph nodes in the woman

Diffuse hyperplasia of the reticuloendothelial elements of the stroma of all lymph nodes studied and also of the spleen was found in the woman Germinal follicles were sparse in the lymph nodes and spleen of the woman in contrast to the man, in whom the numbers of germinal follicles were consistently within normal limits in 3 separate biopsies taken in the course of 6 years The most striking variation from normal, in both the man and the woman, was the presence of mature plasma cells The microscopic appearance of the reticuloendothelial tissue of 6 patients, 3 men and 3 women between the ages of 17 and 53 years, with the acquired idiopathic type of agammaglobulinemia associated with splenomegaly, whose cases were collected from the literature, showed similar features to those observed in the 2 patients Three of the 6 patients had neutropenia and 3 had an acquired hemolytic anemia which was relieved by splenectomy in 2 Abnormally high serum gamma globulin levels were observed in healthy relatives of both of the author's patients and in those of some patients reported by other workers

The Treatment of Snake Bite H L Stahnke, R M Allen, R V Horan and J H Tenery Am J Trop Med 6 323-335 (March) 1957 [Baltimore]

The most commonly recommended treatment for snake bite, i e , the tourniquet, multiple incision, and suction (popularly known as the tourniquet, cut, and suction method) does very little to alleviate the problem of tissue destruction On the basis of 2 illustrative case histories the authors show the superiority of cryotherapy over the tourniquet, cut, and suction method Since snake venoms produce their harmful local effects through the action of enzymes or enzyme-like substances, the use of cryotherapy is definitely indicated Conversely, any technique that permits the venom enzymes to remain concentrated in the body at normal temperatures is providing optimum conditions for tissue destruction Although incision and suction may remove some venom, the most efficient technician can hope to remove only a relatively small part Advantages of cryotherapy are that it prevents rapid absorption of the lethal neurotoxic factor, inhibits bacterial activity, provides ample time for the correct administration of antitoxin, and benefits the emotional condition of the patient by providing a very effective anesthetic action The usual severe pain experienced in pit-viper venenation is absent

Cryotherapy of snake bite requires the following steps 1 A ligature should be placed at once between the site of the bite and the body, but as near the point of entrance of the venom as possible The usual type of tourniquet is not adequate and will permit the spread of the venom A hemostat should be used, especially if the bite is on one of the digits 2 A piece of ice should be placed on the site while a suitable vessel of crushed ice and water is being prepared 3 The member should then be put well above the point of ligation in the iced water Iced water initially is preferred to ice packs, since the thermal conduction in iced water is much greater 4 After the envenomed member has been in the iced water for not less than 5 minutes, the ligature should be removed, but the member should be kept in the iced water for at least 2 hours 5 Then the member is packed in finely crushed ice Since pit-viper venoms may stay in the area of the bite under normal body temperature for 14 hours or more, the cryotherapy will have to continue for a minimum of 24 hours The bite of a snake having a length of 4 ft or more may require 3 or more days of continuous cryotherapy If ice is not immediately available, other methods for reducing the temperature may be employed The most effective mediums are the bottled gases under pressure, such as those in fire extinguishers (carbon techrachloride or carbon dioxide) Frigiderm, ethyl chloride, or freon are especially useful 6 The patient should be kept warm, and after the first 24 hours removal of the enzymes from the site will be hastened if the patient is kept somewhat uncomfortably warm 7 The warm-up after cryotherapy must be gradual It can be accomplished by allowing the water in which the member is immersed to come to room temperature gradually Supplementary therapy is also discussed

SURGERY

Surgical Treatment of Pulmonary Tuberculosis T J Kinsella Dis Chest 31 525-539 (May) 1957 [Chicago]

In commenting on the drastic changes that have taken place in the treatment of tuberculosis during the last decade, the author shows that the older forms of therapy such as pneumothorax, decortication, pneumoperitoneum, phrenic nerve surgery, extrapleural operations, and thoracoplasty were helpful in the control of tuberculosis Thousands of patients who are in good health are living proof of the value of many of these procedures The reason these methods are no longer in extensive use is that the modern methods are better Chemotherapy followed by resection of residual tuberculous disease has largely supplanted prolonged bed rest, collapse therapy, and other treatments The author is concerned chiefly with modern resectional therapy Since this treatment is still in the developmental stage, questions such as how soon and how much are still largely undecided The results also are difficult to assess, although they seem excellent By removal of the tuberculous lesion the period required for treatment is greatly shortened and the future of the patient seems to be safer than with any type of collapse therapy

The time is too short for a fair evaluation of resectional therapy, and the results are as yet clouded by the effects of long-term chemotherapy still being continued The number of patients who underwent resection and had to be readmitted to the sanatorium because of late reactivation of disease has been small, and reactivation has occurred chiefly in those presenting organisms resistant to the drugs, those who early in the program received only short-term therapy, and the deserters who discontinued all treatment soon after surgery As one who for the past 30 years has utilized almost every type of surgical attack on tuberculosis, the author now feels that the present program is the best yet and that, given modern facilities for its use, it is far superior to any other plan of attack now available The risk of death from resectional therapy has been reduced to 0 3% in 311 operations performed on 285 patients in 1954 and 1955 The over-all mortality rate (death within 60 days) in 817 operations carried out in one sanatorium to the end of 1955 was 1 95% The death rate from resectional therapy is also cited for special groups it was zero in children under 14 and 2% in diabetic patients Relapses or recurrences following chemotherapy and resection are closely related to short-term chemotherapy and presence of resistant organisms and to incomplete treatment programs

Intestinal Obstruction Due to Incarcerated External Hernia, with Notes on Non-operative Reduction and Interim Elective Herniorrhaphy W B Gallagher and R H Segnitz Am J Surg 93 771-777 (May) 1957 [New York]

At the Milwaukee County Hospital, 3,676 patients with external abdominal hernia were seen during the decade from 1946 to 1956 This report is concerned with the 245 hernias that were incarcerated and in which intestinal obstruction was proved either at operation or by clinical or x-ray findings Patients with asymptomatic irreducible hernias and those in whom omentum only was caught in the hernial sacs were not included Manual reduction was used in 60 patients, 4 of whom subsequently required emergency operations One of these 4 patients died The procedures used in manual reduction consisted of elevating the foot of the bed and giving a narcotic (morphine or meperidine) An ice bag was frequently applied After the narcotic had allayed the pain, apprehension, and spasm, gentle manipulation with diffuse pressure on the hernial mass was begun The patient himself can be asked to attempt reduction Disappearance of the hernial mass, immediate relief of pain, and subsidence of the symptoms of intestinal obstruction signal a successful reduction Subsequently the surgeon must make frequent checks to make sure that reduction has been accomplished, and elective herniorrhaphy should be performed within a few days Manual reduction was not attempted in exquisitely tender hernias and seldom in those incarcerated more than 24 to 36 hours Narcotics in moderate doses do not mask symptoms and signs of strangulation The authors found that inguinal incarcerations could be safely reduced manually in 30% of the cases, the femoral in 13%, the umbilical in 16%, and incisional defects in 12%

Emergency operations were performed in 181 patients, with 34 deaths (18 7%) Sixty-five of these had simple incarcerations, and 8 of these died The contents of the sac were viable in 82 of those with strangulation, and of these 14 died Of those with strangulated and gangrenous obstructions, 25 were treated by resection and 6 of these died Both patients in whom plication was performed survived, but the 2 in whom exteriorization was performed both died, incision and drainage of abscess was performed in 5, of whom 2 died The 6 whose hernia was inoperable because of complete gangrene all died Two strangulated and gangrenous hernias were found at autopsy The authors conclude that, if manual reduction fails, the simplest, briefest surgical measures to alleviate the obstruction are indicated Gastrointestinal suction decompression, electrolyte balance, fluid and whole blood replacement, and antibiotic "coverage are also indicated If intestine of dubious viability is encountered, resection and anastomosis (by either closed or open method) is the treatment of choice Small patches of gangrene can be inverted by plication sutures With the increasing number of elective herniorrhaphies in infancy, incarceration should become a diminishing problem

Duplication of the Cystic and Common Hepatic Ducts, Lined with Gastric Mucosa A Rare Congenital Anomaly C M Lee Jr New England J Med 256 927-931 (May 16) 1957 [Boston]

The 13-year-old boy whose history is presented began to have recurrent attacks of severe epigastric pain at about 14 months of age The attacks were postprandial and generally subsided in about an hour They became less frequent without specific treatment, and for several years he was nearly free of them, with only occasional episodes at irregular intervals of 3 to 6 months Three years before admission the patient became severely jaundiced, but studies were inconclusive and the jaundice subsided before a diagnosis was made Except for transitory attacks of postprandial pain, he remained well until 2 weeks before admission, when he became slightly jaundiced, with yellow scleras and dark urine, however, his stools remained normal and cutaneous jaundice was not apparent During the week in which examinations and tests were made, he had several attacks of postprandial epigastric pain At operation the gallbladder was removed Frozen sections of the distal portion of the mass showed that it consisted of a double-lumened structure with a common muscularis, lined by biliary epithelium on one side and gastric mucosa on the other The lesion covered the entire common hepatic duct, and resection of it would have necessitated transection of both hepatic ducts proximally and the common duct distally, reconstruction would have required a double choledochoenterostomy, probably involving a Roux-Y anastomosis The alternative was to attempt amputation of the duplication by splitting the common muscular coat, without entering the common hepatic duct The latter course was chosen and was effected by careful scissors dissection, with a T-tube in place as a guide The wall of the common hepatic duct was preserved intact, and no communication between the 2 structures was demonstrated The operation, including appraisal of the frozen sections, consumed nearly 5 hours

The postoperative course was uneventful, and the patient was discharged from the hospital on the 12th day after operation, with the T-tube in place but closed with a rubber band Cholangiograms made through the T-tube at 8 days, 2 months, and 3 months after operation demonstrated gradual recession of the dilatation of the proximal biliary tree The T-tube was removed after 5 months, without untoward reaction The author cites a recent review of the literature on congenital abnormalities of the gallbladder, pointing out that the term double or accessory gallbladder, or vesica fellea duplex applies to 2 more or less complete gallbladders with single or double cystic ducts These are comparable to double kidney, ureter, or uterus in which an extra organ of variable functional capacity is present Approximately 64 cases of such anomalies of the gallbladder in human patients have been reported The term "duplication,' on the other hand although it actually differs little from "double," has by common usage acquired a clear implication of abortive embryonic rests representing incomplete, and usually afunctional, structures attached to an otherwise normal hollow organ The lesion present in the case reported here apparently corresponds to the latter type It is believed to be the first case of congenital duplication of the cystic duct and common hepatic duct, and containing a gastric mucosal lining, ever described

Choice of Therapy for Peripheral Arteriosclerosis E A Edwards New England J Med 256 875-880 (May 9) 1957 [Boston]

As surgical methods become available in the management of peripheral arteriosclerosis, the proper choice of treatment for a particular problem encountered becomes important Major surgery is justified only if life expectancy is adequate How the general expectancy is affected by the presence of peripheral arteriosclerosis is not well documented A study of 100 patients after lumbar sympathectomy offers the encouraging figure of 65% alive at 5 years The author comments on localized versus diffuse arteriosclerosis and emphasizes the importance of evaluating each patient's pathological process to make a proper choice of treatment The localization of arterial obstruction may be judged from the location of claudication pain, palpation, oscillometry of the pulses, and auscultation of the major arteries as well as by arteriography Aortography carries considerable risk and should be avoided if possible Most aneurysms can be delineated through the demonstration of calcification by simple roentgenography Arterial thrombosis and aneurysm are being increasingly emphasized as dangerous complications of arteriosclerosis demanding active treatment Both sympathectomy and arterial reconstruction are useful modes of therapy, but each has its limitations At present, aneurysm stands out as the only certain indication for graft replacement Conservative surgical measures are often successful in the treatment of necrosis

The aims of medical management of the patient with arteriosclerosis are as follows to find and treat concurrent disease, to prevent injury to the ischemic parts, and to treat thrombosis by anticoagulants Medical treatment cannot be expected to change the circulatory status of the limb except in indirect ways, as by allowing one to wait for partial spontaneous improvement after thrombosis, by improving the condition of the heart, or by correction of anemia or polycythemia No vasodilators are effective in arteriosclerosis

Surgical Transplantation of Tumor Cells C T Meadows Am Surgeon 23 247-256 (March) 1957 [Baltimore]

Transplantation of tumor cells in surgical wounds have been reported since 1891 The one fact repeatedly emphasized in the literature is that implantation may occur from practically any type of cancer, located in almost every section of the body Numerous examples were cited in which cancer of the breast, tongue, lip, larynx, rectum, and colon were implanted at operative sites through cancer infection of the wounds by contaminated knives and needles In 1908, Ryall recommended a complete change of gloves, drapes, and instruments and repreparation of the operative site after the biopsy of a malignant tumor is completed and the exploratory incision is closed The perilous effect of tumor cells adherent to the blade of the knife is clearly brought out by several statements which stressed the danger in excising a cancer without the use of cautery and then waiting longer than 2 weeks before the radical operation A case of local recurrence within the abdominal wall 13 years after operation on an ovarian neoplasm was reported between 1930 and 1940 Stimulation of growth and dissemination of tumor cells through the blood and lymph vessels was explained by the dropping of viable tumor cells, which were transferred into the blood vessels by the dissecting knife Many surgeons, in 1936 were discarding the knife after it had been used for the removal of a biopsy specimen of a malignant tumor and continuing the radical operation with another knife or with a second set of instruments This practice, however, was not universal, and the same instruments were still used by some surgeons The present communication reports on the results of examination of material which adhered to the blades of knives used for obtaining biopsies of tumors, particularly breast tumors In some instances the malignant cells were so abundant that their number was comparable to that of erythrocytes on a blood smear of average thickness

Ackerman and Wheat presented in 1955 many new case reports, which aid in making the picture of transplantation more complete Needle biopsy is mentioned as a method of transplantation of tumor cells, as well as skin graft implantations, such as the plasma cell tumor of the chest wall, which was implanted on the donor site of the leg Several subcutaneous implants of tumor cells were reported, such as one following enucleation of a supposed benign thyroid tumor seven years later, implantation of a chondrosarcoma of the femur, and implantation of a carcinoma of the stomach into the abdominal wall scar, this last implantation was removed and the patient was well 5 years after the procedure

A patient with adenocarcinoma of the breast is reported by the author himself Mastectomy was performed elsewhere, and the patient had been followed in the tumor clinic for 2 years One week before death occurred, a nodule was noted in the thigh and was removed It was reported as metastatic adenocarcinoma Postmortem examination a week later revealed extensive pleural metastasis, but no other primary lesion was noted This patient did not have a skin graft The author presents 4 other patients with carcinoma of the stomach, bronchogenic carcinoma, carcinoma of the ascending colon, and carcinoma of the rectum All these cases illustrate transplantation of the tumor cells

Bronchospirometric Investigations Before and After Segmental Resection and Lobectomy for Pulmonary Tuberculosis G Birath, N-P Bergh and E W Swenson Am Rev Tuberc 75 710-723 (May) 1957 [New York]

The unilateral functional loss attending segmental resection and lobectomy was measured with the aid of bronchospirometry in 51 patients with pulmonary tuberculosis for which they had been operated on The relative size of the functional loss caused by the disease itself was also measured in these patients, and that was done with the aid of preoperative bronchospirometry One segment was resected in 18 of the patients and 2 segments in 16, upper lobectomy, frequently combined with the resection of 1 segment and a small thoracoplasty, was performed in 10 patients and lower lobectomy in the remaining 7

The diseased lung had already lost 10% of its normal function before resection in the patients who had undergone resection of 1 segment, for the patients with resection of 2 segments, the functional loss caused by the disease amounted to 20% of the normal value of the involved lung The patients in the upper lobectomy group, although not uniform, had a preoperative unilateral functional loss of about 33%, while the patients in the lower lobectomy group had already lost 50% of the function on the diseased side before the operation Three months after operation these losses were increased in each group, the operated lung having lost about 25% of its normal function after resection of 1 segment, about 33% after resection of 2 segments, 50% to 66% after upper lobectomy-thoracoplasty, and about 66% to 75% after removal of a lower lobe The amount of the functional loss 3 months after the operation was definitely larger than the quantity of resected lung tissue, with the greatest deviations between physiological and anatomic loss being observed in those hemithoraces which had suffered the greatest restriction to ventilatory movements The more extensive resections were followed by larger and more unpredictable functional losses All signs point to the likelihood of functional improvement occurring after the 3 month postoperative period at least up to the end of the first year after the operation Preoperative, intraoperative, and postoperative measures taken in the clinical management of these patients that lead to the best functional results are discussed

Considerations on 162 Patients with Endocranial Metastasis I Pipo and R Tritapepe Minerva chir 12 269-274 (March 31) 1957 (In Italian) [Turin, Italy]

Of 2,531 patients with endocranial neoplasia received in 2 hospitals from 1930 to 1956, 162 had endocranial tumor due to metastasis Metastatic origin of the tumor was ascertained at the operation in 153 patients and at autopsy in 9 The authors studied also an additional group of 66 patients who were not operated on but who had endocranial tumors that almost certainly were metastatic All 66 patients had previously been operated on for malignant tumors or had tumors in some other region mostly the lungs Of the 162 patients 1 was under 20 years of age, 6 were between 20 and 30, 19 between 31 and 40, 78 between 41 and 50, 49 between 51 and 60, and 9 between 61 and 70 The point of origin of the endocranial metastasis could not be ascertained in 68 patients (42 5%) Localization of the primary tumor was unknown in 32% of the patients if the 66 patients who were not operated on are included The lung was the most frequent site of the primary tumor, being involved in 35 8% (42 3% of the men and 17 1% of the women) Carcinoma of the breast was the primary tumor in 28 5% of the women Multiple metastases were more frequent than single metastases (ratio of 3 2) The metastasis was supratentorial in 77% of the patients Twenty-nine of the 125 patients with supratentorial tumors had them in the parieto-occipital region The symptoms appeared less than 3 months before the operation in 73% of the patients Twenty-five patients (16 3%) died within 20 days after the operation Ten of a group of 73 patients survived more than 1 year after the operation One of the patients with carcinoma of the breast survived for 9 months, but the others and those with melanoblastoma survived less than 6 months The authors think that operation is indicated when the patient is in fair general condition and the symptoms of hypertension are the cause of severe suffering Operation is contraindicated when there are multiple endocranial and extracranial metastases and when the subjects are elderly or in poor general condition

Chemical Aspects of Neurinomas of the Stomach H-J Peiper Beitr klin Chir 194 139-157 (No 2) 1957 (In German) [Munich, Germany]

Some reports on neurinomas, although mentioning their localization in the extremities, cranial nerves, and spinal cord, do not mention their occurrence in the stomach, although this localization was described in 1922 The neurinoma-specific rhodiochromic tissue stain introduced by Feyrter in 1950 promoted histological studies on the neurinomas of the gastrointestinal tract The use of this stain disclosed that many neurogenic gastrointestinal tumors had been mistaken for sarcomas, myomas, or fibromas The author believes that in the future reports of neurogenic tumors of the stomach will increase He presents the histories of 2 patients with neurinoma of the stomach, who presented similar clinical pictures On the basis of observations on the first patient the diagnosis of gastric neurinoma was suspected in the second The first patient had had a severe gastric hemorrhage in 1942, the cause of which had not been ascertained In 1956 the patient complained of pains under the left costal arch, he had also noted a hard protrusion in the left side of the upper abdomen, and he had lost a considerable amount of weight Roentgenologic examination of the stomach showed displacement to the right side and downward Laparoscopy revealed a giant tumor with a knobby surface that apparently had no connection with colon or stomach A retroperitoneal sarcoma, a tumor of the spleen or a pancreatic cyst were considered

Laparotomy revealed a neurinoma that originated from the anterior wall of the stomach The tumor, the size of a child's head, was removed, together with the spleen to which it adhered and with the pedicle and the wall of the stomach to which the pedicle was attached The cavity of the tumor was filled with a sanguinous fluid, and its wall was from 0 5 to 1 5 cm in thickness In the second patient the tumor was found to originate from the small curvature of the stomach Because of the wide attachment of the tumor a Billroth 1 gastric resection was performed Histological examination disclosed the neurogenic nature of the tumor During the period from 1945 to 1956, when 412 patients were operated on for carcinoma of the stomach at the surgical clinic of the University of Marburg, 18 patients received surgical treatment for benign tumors of the stomach These 18 included the 2 aforementioned patients with neurinomas, of the remaining 16 patients with benign tumors 11 had polyps, 4 had myomas, and 1 had a lipoma The author recommends early surgical treatment for neurinomas of the stomach, not only because of the threat of fatal hemorrhage but also because of possible malignant degeneration

The Fatal Postoperative Pulmonary Complications in General Surgery W H Becker, K Devens, R Fritz and others Beitr klin Chir 194 203-215 (No 2) 1957 (In German) [Munich, Germany]

During the decade 1945-1954 there were 1,263 deaths among 14,010 patients operated on at the surgical clinic of the University of Giessen Pulmonary complications were responsible for 218 (17 2%) of these postoperative deaths Only 2 other factors caused more postoperative deaths, namely, septic processes and metastases of malignant tumors Fatal postoperative pulmonary complications were nearly twice as frequent (17 2%) as were fatal thromboembolisms (9 7%) Deaths from pulmonary complications were particularly frequent after thoracic operations, that is, they accounted for 83 of 147 (56%) deaths in 1,151 operations on the thorax Of 1,116 deaths that occurred after 12,859 operations (excluding those on thoracic organs) 135, or 12%, were due to pulmonary complications Of these 135 deaths, 97 were caused by bronchopneumonia, 12 by lobar pneumonia, 8 by hypostatic pneumonia, 7 by pleural empyema, 7 by generalized tuberculosis, 2 by extensive atelectasis, and 1 each by pneumothorax and aspiration

The fact that the percentage of fatal postoperative pulmonary complications remained practically unchanged despite the use of chemotherapy and antibiotics is attributed chiefly to the fact that surgical operations are employed more widely While many factors are involved in the development of fatal postoperative pulmonary complications, bronchopneumonia plays a part in about 75% of the deaths, particularly in patients who are in the 7th and 8th decades of life Patients with emphysematous bronchitis seem to be predisposed, since 60% of all those who died of postoperative pulmonary complications showed emphysema on autopsy, compared with only 43% of those who died from other causes Only 1 5% of those who died of pulmonary complications showed atelectasis on autopsy probably because atelectasis is more readily prevented now than was the case formerly by intratracheal suction, respiratory gymnastics, and medical and mechanical circulatory measures These measures together with preoperative examination of the pulmonary function and suitable preparation for the operation are helpful in the prophylaxis of postoperative pulmonary complications

Carotid Artery Surgery in the Treatment of Tumors of the Neck J J Conley A M A Arch Otolaryng 65 437-446 (May) 1957 [Chicago]

The application of the principles of vascular surgery to the carotid arteries has proved helpful in the treatment of tumors in the neck Metastatic cancer invading the carotid arteries, large, enmeshing carotid body tumors, and impending and actual carotid artery hemorrhage present circumstances demanding some type of operation on the carotid artery Intra-arterial pressure readings before and after occlusion are helpful in determining whether an operation on the carotid artery will be lifesaving If the pressure in the distal segment of the internal carotid artery falls by 60 to 70% of its original reading after ligation, a serious complication is likely to develop If the pressure falls by only 20% of its original reading, ligation is likely to prove safe The author reports a series of 31 operations on the carotid and 1 on the vertebral artery The 31 operations on the carotid included 17 free vascular grafts all with autogenous veins, occasionally the saphenous, but chiefly the superficial femoral Ten patients survived the operation Six ipsilateral anastomoses were performed on the internal and external carotid arteries All these patients survived the operation Primary repair of the carotid arteries proved to be a helpful adjunct in carotid artery surgery It was performed 7 times, and 6 patients survived the operation

Bleeding in the carotid arteries is controlled with gentle compression All clamps in use today (Potts, Southwick, and spring types) are traumatizing to the intima of the carotid arteries and should be avoided Gentle compression with fascia lata or tape is preferred Longitudinal wounds resulting from debridement of small perforations, local excisions of cancer in the artery wall, and inadvertent tears are repaired with continuous or individual 00000 nonabsorbable surgical arterial (silk) sutures The stitch penetrates all layers of the vessel wall, but care is taken to prevent inversion of the adventitia In free vessel grafting to a larger defect, two continuous 00000 nonabsorbable surgical arterial sutures are used at each end of the graft The free graft and suture line are bathed in heparine solution during the operation Individual additional sutures may be required to close small leaks A cuff of oxidized cellulose (Oxycel) about the suture line for 5 minutes usually controls all bleeding No heparin is given after the operation

Orthostatic Hypotension in Patients Subjected to Gastrectomy E I Cohen Presse med 65 688-690 (April 13) 1957 (In French) [Paris]

Orthostatic hypotension is characterized by a decline in arterial pressure averaging from 50 to 70 mm Hg accompanied as a rule by an increase in the heart rate—within physiological limits—of 25 pulsations or more Sometimes, however, orthostatic hypotension fails to appear It is well known that orthostatic hypotension can be temporarily relieved by compression of the abdomen and the lower limbs Experimental studies in which these procedures were used separately have shown that, although the characteristic fall in arterial pressure could not be prevented by compression of the abdomen alone, it could be effectually prevented by applying compression to the limbs alone Further studies have also shown that the accumulation of blood responsible for the fall in pressure when the patient assumes an upright position takes place in the venous circulation These findings explain the good results obtained by surgical treatment (saphenectomy) or by ligation of the femoral veins below the inguinal ligament, as advocated by Costantini in patients with orthostatic hypotension The disturbance in the venous circulation in these patients can be attributed to an inadequacy of venoconstriction, which leads to an increase in the vascular bed, a reduction in the flow of blood towards the heart, and a decrease in cardiac output, as in collapse Orthostatic hypotension may therefore be regarded as a special form of collapse which is due to gravity, indeed orthostatic collapse would be a better designation for this condition than orthostatic hypotension

The reduction in cardiac output which explains the clinical picture presented by the patients makes itself felt most in the circulation to the brain, so that the predominant signs are nervous, i e , auditory or visual disturbances, mental disturbances, fainting, and syncope Orthostatic hypotension is thus connected with sympathetic hypotonia and may be encountered in various conditions of which sympathetic hypotonia is a component part, such as Addison's disease or Simmonds disease, after extensive sympathicotomies for the relief of arterial hypertension, and in medullary diseases in which injury to the sympathetic centers is highly probable

The author has recently seen 6 patients with orthostatic hypotension all of whom had undergone gastric resection This procedure, which has not heretofore been mentioned as a cause of orthostatic hypotension, probably acts by injuring the sympathetic system, thus producing a state analogous to that created by sympathectomy in patients with arterial hypertension Syncopal attacks in patients who have undergone gastrectomy are usually attributed to the dumping syndrome, but they may well be due instead to the syndrome of orthostatic collapse Two of the author s patients presented the syndrome in a transient form, the existence of which is not generally referred to in the literature, in fact, the syndrome is usually said to be a chronic condition These transient forms were clinically silent Compression of the lower limbs by appropriate bandaging, taking care not to interfere with the arterial circulation, which proves that the accumulation of the blood takes place in the venous circulation, can also be used as a therapeutic procedure in preventing or relieving orthostatic collapse

Exposed Delayed Primary Skin Grafts A Clinical Investigation J Calnan and F L F Innes Brit J Plast Surg 10 11-24 (April) 1957 [Edinburgh]

Although the application of pressure to grafts is generally regarded as essential to achieving a take neither the amount of pressure required nor how it is to be maintained is stated Their own observations convinced the authors that, whatever pressure might have been applied at the time of bandaging over a graft, this pressure within a matter of hours must approach the vanishing point In addition, they were impressed by the favorable take of patch grafts on granulating surfaces where no pressure and no dressing had been applied For this reason they investigated the necessity for pressure dressings They applied medium-thickness grafts from the thigh to the raw surface on the neck of a woman from whom an area of irradiation dermatitis had been excised No fixation and no dressing was used, but head, neck, and shoulders were immobilized in a prefabricated plaster back shell A stomach tube was used for feeding for the first 3 days to reduce the amount of movement from swallowing By then the grafts were pink and appeared to have taken Fourteen days after grafting the grafts were well healed without loss, the splint was discarded, and the patient was ready for discharge Since these grafts did so well, this method was tried in 25 other patients The results were equally encouraging and show that pressure on grafts is not necessary for their successful take Other disadvantages of pressure dressings include the danger of necrosis if pressure is too great, the frequent failure of well-applied pressure dressings to prevent hematoma formation below a graft, the inability to see collections of blood or serum below a graft, the time needed to apply pressure dressings at operation, the expense of such dressings, and the danger of leaving suture marks where stitches are used to immobilize the graft or dressing

The length of time that skin can survive in the absence of food and oxygen depends on its temperature The higher the temperature, the shorter the time of survival A free skin graft is ischemic until an effective blood supply reaches the underlying dermis, i e , for a length of time that is roughly proportional to its thickness For this reason thin grafts take better than thick ones During the ischemic period the graft must survive by absorption of the serous exudate from its bed—the so called 'plasmatic circulation " Cooling of grafts allows them to survive in vitro for a length of time that is roughly inversely proportional to the temperature The lower the temperature, the longer the time of survival Exposure of skin grafts applied to the body so that they are at room temperature appears to prolong their survival during the time of the plasmatic circulation " The exposure of grafts is practicable and appears to offer certain clinical advantages In some areas, where the application of dressings is difficult or where movement cannot be completely controlled, delayed primary application with exposure of the graft is a satisfactory method for obtaining skin cover It avoids the necessity for bulky dressings and complicated splinting

In 23 of the 25 patients in whom the authors used no pressure, skin grafts were applied 5 to 12 days after the recipient area was prepared The technique followed has been to cut the skin graft, to place it folded on tulle gras in a dry sterile jar, and to store this in a refrigerator at 4 C At the same operation the recipient area created by excision of some offending lesion after careful hemostasis, is covered by a bulky occlusive dressing of dry sterile gauze After five days the occlusive dressing is gently removed and the stored skin applied to the now granulating wound The delay in applying skin grafts does not seem to affect the final results

GYNECOLOGY & OBSTETRICS

Observations on 30 Patients with Eclampsia Treated with Lytic Therapy P Mangione Riv ostet e ginec 12 13-26 (Jan) 1957 (In Italian) [Florence, Italy]

The author reports on 30 patients with severe eclampsia treated with lytic cocktails None of the mothers died Two 5-month old fetuses died, 4 fetuses died of causes not connected with the lytic therapy, and 1 died before the treatment Convulsions disappeared after the administration of the lytic cocktail, the blood pressure values dropped, tachycardia was observed at first but later the rate of the pulse beat dropped, the temperature of the body was reduced An improved blood flow caused the return of the renal function A negative effect of the therapy on the movement of the uterus during delivery was checked with oxytocic drugs The author thinks that the ganglion-blocking therapy prolongs the period of expulsion and that it precludes in part the participation of the patient in the process of expulsion Forceps were used to facilitate delivery in most of the patients The therapy had a beneficial effect on the patients who were subjected to abdominal operation, made possible administration of a low dose of anesthetic, increased the tolerance of the patient to the operation, and had an antishock effect Untoward side-effects in the mothers and in the fetuses were not observed The therapy caused thrombophlebitis in one patient and bronchorrhea in another

Perinatal Mortality in the Unsuspected Diabetic P Pedowitz and E L Shlevin Obst & Gynec 9 524-532 (May) 1957 [New York]

The authors report the cases of 8 of 301 pregnant diabetic women who were delivered of viable infants between January, 1932, and July, 1956 Despite a definite hereditary history in the first 2 patients, it took 3 repeated intrauterine deaths before a study of the carbohydrate metabolism, which revealed unsuspected diabetes, was made A restricted diet, insulin administration, and elective cesarean section resulted in the delivery of normal living infants in successive pregnancies Glucose-tolerance studies are indicated in all unexplained antepartum fetal deaths and should be performed during the first week of the puerperium The cases of 3 pregnant women with preeclampsia showed that in such patients, when the infant is normal or excessive in size for the period of gestation, unrecognized diabetes may be present As shown in 2 of these women, fetal death occurring in utero, with an oversized infant, should not be assumed to be due merely to preeclampsia The recurrence of toxemia in successive pregnancies, as was observed in 1 of the 2 patients, indicates the possibility of some abnormality in carbohydrate metabolism as an underlying causative factor

The 6th patient had a history of 3 early spontaneous abortions and 1 late abortion with fetal malformation A glucose-tolerance test was performed during the 3rd month of her 5th pregnancy This revealed diabetes mellitus The patient was placed on a restricted diet and treated with insulin, and a normal living baby was delivered by cesarean section Although most cases of habitual abortion are not due to diabetes, it may play a role This case also showed that obstetric complications of diabetes may begin many years before clinical recognition The cases of the last 2 patients were illustrative with respect to the size of the infant In the first of these 2 patients, 2 previous pregnancies had terminated in spontaneous deliveries during the 37th week of gestation after the onset of premature labor The living infants weighed 3,760 and 4,086 Gm (8 lb 5 oz and 9 lb) respectively Because of a rising Rh antibody titer, labor was induced during the 36th week of her third pregnancy and a normal living infant weighing 4,120 Gm (9 lb 1 oz) was delivered spontaneously There was no evidence of erythroblastosis and, therefore, a glucose-tolerance test was performed 1 week after delivery This revealed a diabetic curve There is a greater incidence of diabetes in patients delivering oversized infants weighing 4,000 Gm (8 lb 13 oz) or more than in those bearing infants of average weight However, an infant may weigh less than 4,000 Gm and still be excessive in relation to the period of gestation This is generally attributed to miscalculation, but it may be the first manifestation of unrecognized diabetes It took 2 additional pregnancies associated with oversized babies before the diagnosis was made The last patient had been delivered 6 years previously of a living infant weighing 3,370 Gm (7 lb 8 oz) Because of glycosuria and a familial history of diabetes, a glucose-tolerance test was done during the 6th month of her current pregnancy It revealed a frank diabetic curve, and the patient was placed on a restricted diet and treated with insulin A living infant weighing 2,500 Gm (5 lb 8 oz) was delivered spontaneously This case illustrates that, although a large infant is the rule in diabetes, the opposite may occur and that it took more than 6 years for the symptoms of frank diabetes to ensue

Glucose-tolerance studies should be performed on all patients with a poor obstetric history, unexplained intrauterine deaths, repeated episodes of preeclampsia, oversized infants, glycosuria during pregnancy, and in toxemic pregnancies in which the fetus is large for the period of gestation The patient with an abnormal reaction to the glucose-tolerance test during pregnancy has diabetes In patients in whom the hyperglycemia reverts to normal after pregnancy, clinical diabetes can be anticipated in the near or distant future Early recognition and obstetric management of the patient with an abnormal glucose-tolerance curve as a diabetic will result in a marked improvement in fetal salvage

Abdominal Pregnancy A Case Presentation and Discussion W S Yocum J Indiana M A 50 568-570 (May) 1957 [Indianapolis]

True primary abdominal pregnancy is rare, but secondary abdominal pregnancy is not Secondary abdominal pregnancy may to be due to tubal abortion, rupture of the uterus, or mechanisms by which a fertilized ovum or partially developed fetus is extruded into the abdomen It is estimated that there is one abdominal pregnancy in each 2,207 deliveries Many theories have been proposed to explain the development of abdominal pregnancy Probably most such pregnancies result from faulty migration of the fertilized ovum due to some pathological condition in the uterine adnexas The difficulties of the diagnosis and treatment of abdominal pregnancy are explained on the basis of the history of a 33-year-old woman Several internists and gynecologists saw her during her hospital stay, but all agreed to treat her symptomatically and conservatively A diagnosis of abdominal pregnancy in the last trimester is usually easy The patient herself many times will make the diagnosis She will say that the baby is too close to the surface or that a hand or foot is too close, and she can feel it easily Such statements are significant, especially from a multipara

The author lists the following as some of the important points in the diagnosis of abdominal pregnancy persistent abdominal pain, displacement of the cervix, high transverse position of the fetus, signs of fetal death, such as missed abortion or missed labor, existence of an extrauterine mass, the pitocin test of Corwin and McCord, and x-ray findings Once a diagnosis is made, laparotomy is the treatment of choice

It was performed in 90% of the 502 patients reviewed This decision holds regardless of the stage of gestation Most authors believe that the placenta should be left in place in abdomen or pelvis This was done in 80% of the aforementioned 502 patients

Afibrinogenemia in Obstetrics R De Rom Belg tijdschr geneesk 13 575-588 (May 15) 1957 (In Flemish) [Leuven, Belgium]

De Rom presents the histories of 2 women with premature detachment of a normally implanted placenta In the first of these 2 patients excessive bleeding continued even after the uterus had been packed to arrest the hemorrhage It was then found that the blood did not clot The patient was given a transfusion of 1,000 cc of blood, and then hysterectomy was carried out After the operation the clotting of the blood was found to be normal In this patient the diagnosis of hypofibrinogenemia was made in retrospect In the second woman hematemesis and hematuria followed the premature detachment of the placenta, and shock resulted despite the transfusion of 1,000 cc of blood The clotting mechanism of the blood was not normalized until after 500 cc of fresh blood had been administered In this patient the fibrinogen content of the blood was tested repeatedly The author lists the signs and symptoms that characterize the bleeding caused by hypofibrinogenemia or afibrinogenemia and discusses laboratory tests by which the clotting defect can be detected He reviews theories and studies on the pathogenesis of afibrinogenemia in connection with detachment of the placenta If afibrinogenemia is recognized as the cause of defective clotting after delivery, hysterectomy becomes superfluous, but either fibrinogen or fresh blood must be administered In view of the possibility that other factors besides fibrinogen may be involved in the clotting defect, the author prefers the use of fresh blood It is not necessary to use the direct technique of transfusion, since the use of citrate does not interfere with the clotting factors

PEDIATRICS

The Value and Limitations of ACTH in the Treatment of Rheumatic Carditis in Childhood H Wiesener German M Month 2 103-107 (April) 1957 (In English) [Stuttgart, Germany]

The clinical picture of rheumatic fever in childhood is different from that observed in adults While in adults the joint changes are marked, they are only transient in children and may be completely absent at the start of the disease This absence of joint changes causes delay in diagnosis and in treatment The author believes that the term rheumatic fever is to be preferred, because it does not stress arthritic changes and may avoid erroneous diagnosis The author reviews observations on 206 children with rheumatic fever observed during the last 30 years In 147 (71%) the heart was affected There were 22 deaths (11%) Although these children were treated immediately during the first fortnight with high doses of aminopyrine (0 3 Gm 6 to 7 times a day), carditis occurred in 7% In 46 children tonsillectomy was performed without much benefit During the last year the author followed up or examined the case records of 105 children (46 girls and 59 boys) who had suffered from rheumatic carditis during the last 30 years and had been treated with various drugs

Between 1951 and 1955 21 children with rheumatic carditis were treated from the onset of illness with a combination of aminopyrine (0 3 Gm 4 to 6 times daily) and corticotropin Small children received at first 20 mg of corticotropin 4 times daily, while school-age children were given 25 mg 4 times daily, after 10 to 12 days the dose was reduced by 5 mg daily The children were followed up for the next 1 to 2 years The results were compared with those of previous treatment using only aminopyrine or salicylates Combined aminopyrin-corticotropin treatment produced significantly better results pain subsided more quickly, a feeling of well-being returned earlier the clinical signs disappeared more quickly, and recurrences were less frequent However, routine use of corticotropin is not recommended The combined treatment is indicated for acute fulminating pancarditis and in the absence of a response to aminopyrine, but not for recurrences

Present Indications for Exchange Transfusion in the Newborn T Boreau and G David Presse méd 65 715-717 (April 17) 1957 (In French) [Paris]

Exchange transfusions may be indicated in three different groups of newborn infants (1) those with hemolytic disease due to anti-Rh isoimmunization, (2) those with hemolytic disease due to anti-A and anti-B incompatibility, and (3) those born prematurely with severe neonatal jaundice but with no evidence of any blood incompatibility The relationship that exists between the frequency of neurological complications, the intensity of the jaundice, and the high level of bilirubinemia was first noticed in infants with hemolytic disease due to anti-Rh isoimmunization, and the critical level of bilirubinemia has since been shown to be about 18 to 20 mg per 100 cc Experimental studies in which it was demonstrated that the same bilirubin concentration (40 mg per 100 cc) produced in vitro a reduction of 67% in the oxygen consumption of cerebral tissue from the newborn rat but one of only 22% in the adult rat may explain why the lesions of kernicterus are nonspecific and why their topography, though more diffuse, is similar to that of lesions which are purely anoxic These experimental findings may also explain why jaundice in the adult, even when accompanied by high levels of bilirubinemia, is not complicated by neurological lesions comparable to those found in the newborn Finally, they seem to suggest that the same mechanism is responsible for the neurological lesions in severe jaundice resulting from various causes

Exchange transfusion is unquestionably effective in combatting hyperbilirubinemia, but it is not equally indicated in all types of neonatal hemolytic disease The principal indication is found in infants of the first group, for whom exchange transfusion is an emergency measure to be instituted at once if the disease is clinically apparent in the first hours of life Delay or abstention is warranted only in certain benign cases Exchange transfusion is also indicated in infants in whom recognition of the existence of hemolytic disease due to anti-Rh isoimmunization has been delayed Discovery of the disease during the dangerous period of the 3rd or 4th day, when it is in its ascending phase and the signs are progressing, requires immediate exchange transfusion to prevent kernicterus Bilirubin estimates should be made every 12 hours or oftener, and the exchange transfusion should be repeated if the bilirubin level remains above 20 mg per 100 cc Children without signs of kernicterus seen after the 5th day will usually not need exchange transfusion unless the bilirubin level is very high, but when kernicterus is already clinically apparent, exchange transfusion may be tried in the hope of preventing late sequelae, although it does not seem to help the immediate neurological condition

Exchange transfusions should be given to infants in the 2nd group only if they are affected by severe forms of anti-A or anti-B hemolytic disease, as shown by the intensity of the jaundice and a high level of bilirubinemia Exchange transfusions in premature infants weighing less than 1,800 Gm involve certain risks, even when well supported, they may increase preexisting anoxia, so that the benefit to be obtained from the reduction in bilirubinemia is offset by the lack of oxygen They should therefore be given to infants in the 3rd group only if the bilirubin level exceeds 18 mg per 100 cc Bilirubin assays in these infants should be continued for longer periods than in those in the other 2 groups, because the abnormal neurological signs may appear as late as the 7th day

Estimates of the bilirubin level in the blood are subject to wide variations and should therefore be carefully checked for accuracy when used as guides to treatment Full value should also be given to the clinical picture and especially the intensity of the jaundice

Artificial Hibernation in Newborn Infants L de la Villa Rodríguez and A Fuertes Bello Rev clín españ 64 85-97 (Jan 31) 1957 (In Spanish) [Madrid, Spain]

Artificial hibernation with chlorpromazine was induced in 26 newborn infants with shock due to obstetric operations, mainly with forceps Other indications included pneumonia from aspiration of amniotic liquid, acute bacterial or virus infection, and erythroblastosis, as a preliminary to exchange transfusion The drug was given in doses which varied between 1 5 and 1 8 mg per kilogram of body weight The total dose of the drug was dissolved in 2 cc of saline solution and 2 drops of the solution thus prepared was administered to the infants at hourly intervals for a period which varied between 24 and 36 hours The sooner the treatment was started the better were the results Satisfactory symptomatic results were obtained in all cases (100%) Six patients died from causes independent from and beyond control of the treatment

Behaviour Problems in Juvenile Diabetics P Katz Canad M A J 76 738-743 (May 1) 1957 [Toronto]

The author reports on a special group of 26 juvenile patients, 16 male and 10 female, between the ages of 3 and 21 years with diabetic mellitus, who at the onset of their disease were between the ages of 1 and 12 years and who in the course of 6 years were admitted repeatedly to a children's hospital, partly because of infections and partly because of the inability of the parents to control the patients' diabetes Eleven of the 26 patients had behavior problems which were revealed by social histories, psychiatric consultations, and personal inquiries Of the 11, 9 refused to follow their diets Six manipulated their diabetes to achieve their own purposes

The diabetic status of a patient may vary with his emotional state because of alterations by the patient of his therapeutic regimen or because of metabolic reactions to situational life stresses The major etiological factors in the high incidence of behavior problems in juvenile patients with diabetes seem to be (1) an unsatisfactory home situation, made worse by the presence of a diabetic child and (2) the regimentation of the patient's life necessitated by the current therapy of diabetes A physician who assumes the management of a juvenile patient with diabetes must devote time and effort towards establishing a good physician patient relationship Instead of becoming angry and scolding the patient—the usual parental response—for dietary indiscretions or neglecting his insulin injections, patience and understanding are suggested, with a firm "failure to approve' of irrational rebellion The parents and the child should be thoroughly acquainted with the nature and the management of diabetes and its complications While they must be convinced of the seriousness of the disease, they should not be terrorized by it, for overanxiety on the parents' part will increase the tension within the home An attempt should be made to alleviate the sense of guilt that is so prevalent among the parents of diabetic children Outside activities should be encouraged Summer camps for juvenile patients help to ease the feelings of loneliness so often present by giving the child a chance to associate with other diabetic patients of his age Sending the child to summer camps also gives the parents a brief rest from the strain of controlling a diabetic child

Partial Cystic Fibrosis of the Pancreas A Clinical Entity G G Caudill J Iowa M Soc 47 244-248 (May) 1957 [Des Moines]

The author describes 3 cases of cystic fibrosis of the pancreas in a 26-month-old boy, a 5-month-old boy, and a 4-year-old boy The case of the first patient was typical of the disease, with involvement of both the pancreas and the respiratory tract The patient was in good health until a few weeks before his first admission to the hospital with a diagnosis of dehydration and possible whooping cough The attending physician believed that the electrolyte balance was out of proportion to the patient's vomiting and diarrhea, but no explanation was found When the diagnosis of whooping cough could not be confirmed, allergy was suspected as the cause of persistent paroxysmal cough During a later admission, the patient was treated intensively for asthma without clinical response Attention was then directed to the possibility of cystic fibrosis of the pancreas, and the diagnosis was confirmed by the sweat test

The cases of the 2 other patients illustrated the fact that patients with cystic fibrosis of the pancreas need not have involvement of both the pancreas and the respiratory tract and that such involvement may manifest itself independently The 5-month-old baby boy was suspected of having cystic fibrosis of the pancreas because of his poor weight gain (despite a good appetite), repeated respiratory infections, and typical roentgenographic findings (emphysema, atelectasis, and pneumonia), but this diagnosis was dismissed because of normal stools and normal tryptic activity An older brother had a definite history of asthma and consequently an examination for allergy was done Because of the 2+ to 3+ skin reactions, the patient's symptoms, and the positive family history a diagnosis of asthma was made For several years, the patient showed a good clinical response to the antiallergic therapy but then his wheezing became worse and failed to respond to epinephrine or cortisone The results of a sweat test showed abnormally high electrolyte values, and a diagnosis of partial cystic fibrosis of the pancreas was made in the absence of the intestinal component The third patient was admitted to hospital because of abnormal stools noted since birth A diagnosis of cystic fibrosis of the pancreas was not seriously considered at first, for there was no history of an unusual number of respiratory infections, and a roentgenogram of the chest showed no evidence of emphysema and atelectasis The absence of trypsin in the stools and duodenal drainage further confused the issue until it was realized that the respiratory component need not be a part of the disease The diagnosis was confirmed by the detection of an abnormality in sweat electrolytes The presence of clubbing of fingers and toes, in the absence of any detectable pulmonary lesions, was an interesting finding

The sweat test is a simple procedure Sweat electrolyte values in patients with cystic fibrosis were found to vary from 60 to 160 mEq per liter (*J A M A* **160** 846 [March 10] 1956), whereas in controls the range was from 4 to 80 mEq per liter These differences are of definite statistical significance When the sweat electrolyte content of the complete and the 2 types of partial cystic fibrosis of the pancreas are compared, there is no statistical difference

A Survey of Accidental Poisoning Cases in Children M S McIntire and J Buglewicz Nebraska M J **42** 235-242 (May) 1957 [Lincoln]

Of 310 patients with accidental poisoning by inhalation and ingestion who were admitted to hospital in the course of 1 year, 296 were children Poisoning from ingestion had occurred in 292 of the children Medicines found around the home were ingested by 148 (50 7%) of the 292 children and analgesics (mostly aspirin) by 79 (27%) Of the latter, the aspirin was known to be of the baby type in 40 and of the adult type in 6, in 33 the type was unknown Sedatives, laxatives, and antihistamines were other medicines which were ingested Pesticides were responsible for the poisoning in 41 children (14 04%) cleaning, polishing, and sanitizing agents in 40 (13 7%), petroleum distillates in 28 (9 6%) cosmetics in 10 (3 4%), and multiple agents in 6 (2%), the ingested substance was unknown in 7 (2 4%) Miscellaneous items such as toad stools, paints, and cigarettes were responsible for the poisoning in 12 (4 10%), carbon monoxide, illuminating gas, lead, and smoke produced poisoning by inhalation in 4 children

Of the 292 children who ingested poisons, 55 spent a total of 112 days in the hospital Aspirin, pesticides and petroleum distillates accounted for 75 (67%) of the 112 hospital days No conclusion concerning the value of lavage in ingestion of petroleum distillates or of furniture polishes could be drawn because of the small number of such cases There were more cases among boys than girls in all age groups except the 4-to-5-year and 5-to-9 year groups, but the number of patients in these groups was too small to be statistically significant Of the 296 children, 290 (98%) were under 5 years of age No racial difference was noted in the incidence of the type of poisons ingested In more than 50% of the children the ingestion occurred between 8 a m and 5 p m, and about 33% of the cases occurred in the afternoon Of the 14 cases of poisoning in adults, 9 were produced by inhalation and 5 by ingestion There were no deaths among the children One woman died of salicylic acid poisoning

Study of an Epidemic of Infantile Gastroenteritis Due to O111 B4 at the Brussels Center of Puericulture and Pediatrics D Markiewicz Acta pædiat belg **10** 227-242 (No 5 and 6) 1956 (In French) [Brussels]

Study of the stools of some 200 children aged less than 3 years admitted to the Centre de Puericulture et Pediatrie from the beginning of March to the beginning of July, 1956, revealed the presence of the pathogenic strain of Escherichia coli O111 B4 in 22 of the patients Cases of gastroenteritis due to Esch coli are extremely rare in infants fed at the breast or on mother's milk, probably because infants so fed have a higher reserve of sterilizing hydrochloric acid in the stomach and a different intestinal flora The age of weaning is especially critical All the children in this series were being artificially fed

The symptoms caused by the infection are usually nonspecific, ranging from simple diarrhea without impairment of the general condition to those of the most severe form with circulatory collapse and nervous involvement The diarrhea, which is constant, is tenacious and unaffected by diet or antibiotics Vomiting and loss of weight are common The simple dyspeptic form of the disease, with diarrhea, vomiting, and a more or less elevated temperature, but a good general condition, was presented by 9 of the children The diarrhea was of the usual resistant type in all but 3, in whom a normal state was restored within 5 days by dietary measures alone The other 13 children, 8 of whom had been hospitalized for various disorders, had the more severe forms of gastroenteritis with impairment of their general condition Only 4, however, were in a serious state, and all but 1 recovered, so that the mortality rate was fortunately low (5%)

The epidemic character of the disease was obvious in the children in whom it appeared during hospitalization for other reasons These children, with the exception of 2 premature infants, were kept in rooms with from 2 to 4 beds The chronological and topographical spread of the disease was significant, but the problems connected with its origin and the mode of transmission could not be resolved The question of epidemicity did not, of course, arise in connection with the children who were hospitalized because of established gastroenteritis

The value of coprocultures, both as a guide to diagnosis and treatment and as a help in prophylaxis, cannot be overemphasized Examination of the stools should be carried out routinely in infants on admission and also in the adults who are brought in contact with them, especially the nurses and mothers in the maternity departments Children found to be infected should be isolated at once and kept in isolation until their discharge, even though the stool cultures may have become negative Symptomatic treatment, including rehydration in severe cases, is the first requirement The use of antibiotics has significantly reduced the death rate in gastroenteritis due to Esch coli, but a serious problem is being created by the emergence of antibiotic-resistant strains Esch coli of the O111 B4 strain, which was responsible for the disease in these children, has been found resistant to streptomycin (76%), to aureomycin (12%), and to chloromycetin (22%) Attempts are being made to meet the problem of increasing drug resistance by the use of new antibiotics, combined either with one another or with one or more of those already established

DERMATOLOGY

Evolution of Therapeutic Concepts Relating to Acute Eczema P Rimbaud Presse med 65 764-765 (April 24) 1957 (In French) [Paris]

The last 20 years have seen a change in the frequency with which the various clinical types of eczema occur Genuine essential eczema, seen in patients of arthritic stock, intermixed with manifestations of lithiasis or respiratory complications, is becoming rarer, while infectious eczemas, with their secondary manifestations and their tendency toward generalization, and eczema-like dermatites due to accidental, occupational, or drug sensitization are becoming more common The change in therapeutic methods, however, has not corresponded too closely to the clinical changes The methods in use at the beginning of the century were comparatively simple each of the 3 types of clinically recognized eczema—artificial dermatites, eczematization, and eczema as a disease—was met by a special form of treatment which consisted of suppression of the noxious contact for the first, local treatment for the second, and attempts to alter the terrain for the third The new pathogenic concepts arising out of investigations into anaphylaxis, allergy, colloidoclastic shock, and humoral instability, together with the therapeutic procedures they suggested, then began to be hastily applied to the field of dermatologic pathology Most of the methods introduced are still being used indiscriminately by many practitioners in all cases of acute eczema, whatever its cause, usually in association with strict diets and supplementary cholagogues and choleretics Most of the patients hospitalized on the author's service had previously been given treatment of this kind with practically no effect

The types of acute eczema most commonly seen today are those of external origin—accidental, occupational, or medicamentous Eczemas of this kind usually have a protracted course characterized by unexpected and inexplicable relapses Suppression of the allergen is not enough to cure these conditions because the skin, having once had its reactive forces set in motion by a specific allergen, seems to remain under tension and to react anew to agents of all kinds, e g, scratching, light, heat, and emotion Infection, too, must be considered because all forms of externally caused eczema and many of those that are constitutional readily become infected during an acute attack In addition, many are primarily bacterial in origin

Rapid improvement in acute eczema can be secured only by general treatment, because local treatment must necessarily be limited for several weeks to the use of emollient and sedative preparations free from any possible sensitizing agent The sole exception to this rule is hydrocortisone ointment, which can be used in treating limited eczemas The initial treatment of choice, therefore, whatever the cause of the eczema, appears to be a combination of an antibiotic and an anti-inflammatory agent, e g, penicillin or a compound with an oxytetracycline base and cortisone or one of its derivatives Combined therapy of this kind usually produces a rapid improvement in all the clinical signs and also leads to increased tolerance for topical preparations, such as those with a base of ichthyol or tar Prolonged treatment with repeated courses of Δ-1-dehydrocortisone may be needed to consolidate the cure, but they can be given without inconvenience Other measures, such as protection from light or occupational irritants, the use of cholagogues, hormone therapy, and those that are intended to modify the terrain or increase functional activity in essential eczema can be effectively decided on only after the acute attack has been checked Each patient should be separately studied so that he can be given the basic treatment that best meets his needs

OPHTHALMOLOGY

Observations on the Therapeutic Effects of Trypsin Administered Intramuscularly in Ophthalmology A Gennaro and M A Romagnoli Minerva med 48 1519-1521 (April 28) 1957 (In Italian) [Turin, Italy]

Sixty-three patients with various eye diseases characterized by inflammation and edema were given intramuscular injections of 2 5 mg of trypsin in oil suspension every 12 hours for 2 days and once a day thereafter until the edema or the inflammation had disappeared Very good results were obtained in 15 patients with ocular trauma, the edema was totally absorbed after 48 hours of treatment Fair results were obtained in 2 patients with commotio retinae, and poor results were obtained in patients with post-traumatic hypohemia Very good results were obtained in patients with uveitis The hypopyon disappeared after 3 days of treatment in a 70-year-old patient with hypopyon keratitis, and the inflammation of the cornea disappeared after 6 days of treatment Poor results were obtained in patients with epidemic keratoconjunctivitis The authors believe that trypsin can be used instead of cortisone in patients with inflammation of the eye whenever cortisone has no effect or is contraindicated Very good results were obtained in patients with retinal venous thrombosis if they received early treatment Disappearance of the retinal alterations and complete return of the retinal function was obtained after 20 days of treatment in a 45-year old patient with thrombosis of the central vein of the retina The authors think that best results can be obtained in patients with thrombosis if the therapy is applied before occlusion has set in, once the occlusion has set in the therapy has a beneficial effect on the absorption of the edema and of the hemorrhage but has no effect on the pathogenetic mechanism of the occlusion Trypsin therapy has no effect on patients with retinopathies due to diabetes or diseases of the kidney The treatment was not interrupted because of complications due to therapy

THERAPEUTICS

The Significance of Bacterial Resistance to Drugs in Pulmonary Resections for Tuberculosis D V Pecora and D Yegian Am Rev Tuberc 75 781-792 (May) 1957 [New York]

Early tuberculous complications and late results of pulmonary resections were studied in 111 patients operated on whose sputum and/or excised tissue yielded tubercle bacilli by culture One hundred twenty-seven operations performed on these patients over a period of 6 years were available for analysis An attempt was made to correlate the laboratory resistance studies with the early and late clinical results In vitro drug susceptibility tests were performed with streptomycin, aminosalicylic acid, and isoniazid Organisms were considered susceptible to viomycin and pyrazinamide if the host had not received these drugs previously The incidence of early complications did not seem appreciably influenced by the number of effective drugs administered, since the proportion of complications with none, 1 2, 3, or more effective drugs followed no definite pattern The number of drugs to which resistance was demonstrated and the incidence of early complications was a reflection of the extent of disease present at the operation The early results with 1, 2, 3, or more effective drugs were very similar The early results obtained without effective drug coverage were not unfavorable when there was little disease in the surgically treated lung The incidence of unsatisfactory late results increased over the incidence of early complications in those patients in whom 1 effective drug or less was administered, and the incidence of early and late results was about the same in those in whom 2 or more effective drugs were employed With the passage of time the patient who received 2 or more effective drugs tended to do better than one who had received less Both early and late results were related more to the extent of the disease in the surgically treated lung than to any other factor

It seems justifiable to conclude that the mere presence of organisms resistant to drugs is of little importance provided that other effective drugs are available One effective drug seems to provide protection against the occurrence of early postoperative tuberculous complications Two or more drugs seem to provide better protection against late unsatisfactory results than does 1 drug An important factor influencing early and late results is the amount of pulmonary disease present, which probably reflects the number of tubercle bacilli harbored by the host

Indications for Radioiodide Treatment of Thyrotoxicosis A Pihl and L Eldjarn Tidsskr norske lægefor 77 295-298 (April 1) 1957 (In Norwegian) [Oslo]

The use of radioiodide in the treatment of thyrotoxicosis is regarded as the method of choice in selected cases In the Norwegian Radium Hospital radioiodide treatment was applied in 14 selected cases of thyrotoxicosis where surgical or medical treatment had failed or was unsuited, and the favorable results reported from other countries seem to be confirmed The period of observation is too short to allow a definitive evaluation of the results To date no case of cancer of the thyroid attributable to radioiodide treatment has been described, although the treatment has been used in many clinics for over 10 years as a routine method in uncomplicated thyrotoxicosis of adults Since the latent period for possible development of cancer after radioiodide treatment is long, the authors find application of the treatment justifiable in patients aged 50 or over In children and young persons, on the other hand, care must be exercised in the use of radioiodide both for diagnostic and for the therapeutic purposes, as the thyroid gland in the young seems to have greater tendency to develop cancer on radiation influence

Cobalt Therapy as Cause of Euthyroid Goiter H Otto Ztschr ges inn Med 12 428 (May 1) 1957 (In German) [Leipzig, Germany]

The author presents the case of a 16-year-old girl in whom cobalt and iron were used in the treatment of a hypochromic sideropenic anemia There were no signs of goiter before treatment, but when it was terminated a goiter and a somewhat decreased basal metabolic rate were observed The author believes that the goiter was caused by the cobalt therapy, the girl having received a total of 417 mg of metallic cobalt, together with large doses of iron and small doses of vanadium and copper He estimates that the total dose of cobalt given to this girl was more than twice the recommended maximal dose Hyperplasia of the thyroid with hypothyroidism after cobalt therapy has been reported by Blumgart, who noted goiter in 3 of 5 patients after cobalt therapy, myxedema developed in 1 of the 3 patients All the symptoms disappeared after the cobalt therapy was discontinued Blumgart assumed that the hyperplasia of the thyroid was a toxic side-effect of cobalt therapy Although these secondary effects of cobalt therapy are not serious, the author believes that they deserve attention, since cobalt-iron combinations are now widely used in the therapy of secondary anemias

Herpes Zoster Treated with Immune Globulin V J Cirincione J M A Georgia 46 210 (May) 1957 [Atlanta]

The author gave intramuscular injections of immune globulin to 3 patients with herpes zoster Two were men, aged 46 and 47, respectively, who had had symptoms of herpes zoster for about 3 days when the first injection of immune globulin was given In both patients the severe pain ceased after the third injection of immune globulin The third patient was a 57-year-old woman, in whom herpes zoster had existed for 4 weeks when the first injection of immune globulin was given The eruption was subsiding, but severe hyperesthesia involving the right intercostal area and pain had persisted She obtained no relief from 5 injections of 20 cc of immune globulin given daily for 5 days When last heard from, two weeks after cessation of treatment, she needed sedation and was still unable to return to her position as a teacher While no definite conclusions can be drawn from these 3 cases, it appears that immune globulin is superior to the customary treatments for pain and neuralgia of herpes zoster The duration of the disease before treatment with immune globulin, however, may be a factor in the response

Deltacortisone in the Treatment of Ascitic Cirrhoses L de Gennes, B Mathieu de Fossey, L Moreau, H Bricaire, R Tourneur and Janson Presse med 65 709-712 (April 17) 1957 (In French) [Paris]

The effect of deltacortisone in ascitic alcoholic cirrhoses was studied in 32 unselected patients, some of whom were threatened with hepatic coma Seven of the patients had atrophic and 25 had hypertrophic cirrhosis The doses given usually amounted to from 30 to 40 mg a day, and the period of treatment ranged from a minimum of 12 days to a maximum of 10 weeks A suitable average seems to be about 5 weeks, only in certain resistant cases was treatment continued for a longer period The patients were kept on a low-salt diet and were given a B complex vitamin preparation and, in some cases, potassium chloride The usually fatal prognosis of atrophic cirrhosis was not altered by the treatment, and 6 of the 7 patients died By contrast, the excellent results obtained in 16 of the 25 patients with hypertrophic cirrhosis undoubtedly give deltacortisone an important place in the treatment of ascitic cirrhoses Ascites and disturbances of water and salt metabolism are the elements of the cirrhotic syndrome principally benefited by the hormone The best results were of course obtained in patients in whom liver function was not too severely impaired, because no treatment can be expected to compensate for a liver whose functional capacity has been so severely damaged that it is practically nonexistent

The polyuria and natriuria observed in the patients who responded favorably to the treatment seemed to amount to a genuine release inaugurating, if not the cure, at least the stabilization of the disease Thus stabilization has apparently been obtained in 7 of the 16 patients benefited by the treatment as shown by a follow-up of from 3 to 12 months Deltacortisone undoubtedly acts, not by affecting the liver directly, but by improving the patient's general condition The removal of the ascitic barrier, the reduction of fever, and the restoration of appetite, which is especially important in these patients, apparently help them to surmount a crisis in the course of the disease, after which the liver is enabled gradually to recover its functional capacity

Hypothermia Due to Phenylbutazone M Cappio Riforma med 71 390-393 (April 6) 1957 (In Italian) [Naples]

Phenylbutazone had a marked hypothermic effect on 4 patients with typhoid fever, 5 with brucellosis, and 1 with malignant granuloma Nine patients were 13 to 30 years of age and 1 was 62 The body weight of each patient was between 37 and 68 Kg (average 51 7) Each patient was given an intramuscular injection of 0 013 to 0 007 Gm of phenylbutazone per kilogram of body weight One patient suffered a violent psychomotor agitation, multiple hallucinations, and some delirium, these symptoms, which lasted for 1 day, were checked with sedatives and by discontinuing the administration of phenylbutazone Weakness and profuse perspiration at times combined with hypertension and tachycardia were observed in the rest of the patients In 9 patients phenylbutazone was combined with chloramphenicol Chloramphenicol was not believed to be the cause of the hypothermia Phenylbutazone is believed to have a central antithermic effect which affects only altered thermoregulatory centers

Treatment with Oxygen for Disturbances of Peripheral Circulation J Meng and W Rieben Schweiz med Wchnschr 87 525-528 (May 4) 1957 (In German) [Basel, Switzerland]

More than 600 intra-arterial and subcutaneous insufflations of oxygen were given to 37 patients with disturbances of peripheral circulation who were divided in 3 groups according to Fontaine's classification The first group consisted of 9 patients in stage 4 with occlusion of the iliac, popliteal, and femoral arteries Only partial improvement with change from moist to dry gangrene resulted from oxygen insufflation alone, and definitely good results with disappearance of pain and improvement of claudication resulted from combined treatment with sympathectomy and oxygen therapy in 4 patients The second group consisted of 9 patients in stage 3, 7 of whom obtained good results and 2, therapeutic failures Of the remaining 19 patients in stage 2, 3 with occlusion of the iliac artery were therapeutic failures, 1 of these was improved by high lumbar sympathectomy Sixteen patients with localized obliterations obtained more or less good results from oxygen therapy alone

Oxygen therapy may be considered as a valuable addition to the conservative methods of treatment of patients with disturbances of the peripheral circulation, since gratifying improvement was obtained with this therapy in 27 (73%) of the 37 patients The authors, however, caution against the use of the method without any reservations and without appropriate indications Every patient who is suspected to have a disturbance of circulation must be subjected to a thorough angiological study in order to establish the indications for the most suitable therapy, and every patient must receive individual treatment Surgical therapy, including vascular grafts and sympathectomy, takes the first place in patients without contraindications to operation Oxygen therapy is the most successful conservative method in the presence of contraindications to surgical treatment The mechanism of action has not yet been elucidated, but its effect seems to depend on a reactive, prolonged hyperemia with increased blood perfusion in muscles and skin Oxygen insufflation should be given a trial in patients with chronic varicose ulcers Patients with occlusion of the femoral artery may show a better response than patients with occlusion of the popliteal artery and combined occlusion of popliteal and femoral arteries In patients with the distal type of vascular occlusion, combined treatment with oxygen and sympathectomy seems to be the method of choice

Experimental Study of BZ 55 P Gonnard and J Dalion Presse med 65 777-779 (April 24) 1957 (In French) [Paris]

The effect of BZ-55 was studied in animals to determine its toxicity (acute and chronic), its hypoglycemic potency, and the histological changes produced by its administration in various organs, especially the pancreas Rabbits given a dose of 0 70 Gm per kilogram of body weight in a single intravenous injection invariably died within 15 or 20 minutes, those given doses of 0 65 Gm per kilogram of body weight or less invariably survived Administration of the drug in fractionated doses, e g, 3 injections at intervals of 1 hour, was also followed by 100% survival, even when the total dose was much higher than 0 70 Gm per kilogram of body weight, thus several rabbits were given doses ranging from 1 2 to 1 4 Gm per kilogram of body weight, and all survived Moreover, the simultaneous injection of 5 cc of hypertonic glucose solution effectively protected the animals against the harmful action of the drug A rabbit given a single dose of 1 Gm per kilogram of body weight of BZ-55 with glucose suffered no ill effects, although the same dose given the next day without glucose led to its death within a few minutes Glucose also acts as an antidote, preventing death when injected from 5 to 10 minutes after BZ-55, even when the animal is already apparently in a coma Death from BZ-55 therefore seems to be due not to the actual toxicity of the drug but to the hypoglycemia it induces Exact determination of the lethal dose did not appear advisable because it was necessary to use alkaline solutions for intravenous injection and the supplementary factor of toxicity so introduced could not be checked All the findings, however, showed that the lethal doses in animals, whether the drug was given orally, intravenously, or intraperitoneally, were very high in relation to the effective doses, i e, those capable of inducing an appreciable hypoglycemia

BZ-55 has an unquestionably hypoglycemic effect in normal animals and also in those with alloxan-induced diabetes, but the extreme variability with which animals respond to alloxan makes it impossible to define the dosage of the drug or the duration of its action Experiments showing that the hypoglycemia induced by BZ-55 is not modified by the subsequent injection of adrenalin seem to prove that BZ-55 keeps adrenalin from mobilizing the glycogen in the liver

Histological study of the pancreas in guinea pigs, rats, and rabbits given varying doses of BZ-55 showed changes in the A cells, no changes in the B cells, and an increase in the number and size of the islands of Langerhans Attempts to determine the mechanism by which BZ-55 acts produced no clear-cut results, but the indications are that its efficacy is related in some way to the existence of a certain amount of insulin in the pancreas

Pulmonary Eosinophil Syndrome Treated with Prednisone Two Cases E Andersson Ugesk læger 119 462-464 (April 11) 1957 (In Danish) [Copenhagen]

In two cases of pulmonary eosinophil syndrome with prolonged course, both in men aged 20, administration of prednisone after tuberculosis was excluded gave good results The diagnosis is primarily difficult to make, and prednisone treatment can be considered only when tuberculosis has been excluded

PHYSIOLOGY

Influence of Mineral Intake on Bone Density in Humans and in Rats D E Williams, B B McDonald, E Morrell and others J Nutrition 61 489-505 (April) 1957 [Philadelphia]

The purpose of the investigations described was to study the effects on bone density of controlled changes in the mineral content of the diet and to assess the bone index as a measure of calcium status The work in 1948 to 1949 involved measurements of bone density on a group of young adults who reported that their customary diets were low in milk Comparable measurements were made after their usual diets had been supplemented with milk Beginning in 1950, bone density values were obtained for young women serving as subjects for a metabolic experiment in which the diets supplied calcium and phosphorus at low levels during periods of restriction and at or above recommended levels when supplemented with dicalcium phosphate or natural foods. Such a study afforded the opportunity to compare the bone densities of the same subjects on their self-chosen diets and on controlled diets at both restricted and optimal mineral levels. In addition, comparative measurements were made on a series of rats, both young and mature, on diets of markedly different calcium content. In the growing rat bone density measurements from x-ray photographs were adequate to detect the influence of different levels of dietary calcium, in the mature rat and the young human no changes were observed.

The Occurrence of Decompression Sickness Following Denitrogenation at Ground Level and Altitude. J. P. Marbarger, W. Kadetz, D. Variakojis and J. Hansen. J. Aviation Med. 28:127-133 (April) 1957 [St. Paul]

Decompression sickness not unlike that experienced by deep-sea divers during ascent has been reported during simulated flights in low-pressure chambers as well as during flight in nonpressurized aircraft at about 25,000 ft. When flying personnel at ground level prebreathe 100% oxygen for a period of time prior to high-altitude aircraft flight in nonpressurized cabins, the incidence of symptoms of decompression sickness is substantially reduced. The authors investigated the rate and volume of nitrogen eliminated by 33 healthy young men sitting at rest for a 2-hour period, breathing 100% oxygen at ground level and at simulated altitudes. The amount of oxygen inhaled by each subject during the denitrogenation procedure was also estimated. Denitrogenation was accomplished at ground level and at 8,000, 12,000, 18,000, and 22,000 ft. simulated altitude in a low-pressure chamber. The volume of nitrogen, the volume of expired air, and the volume of oxygen inspired were expressed in terms of standard temperature pressure and dry (STPD). These volumes were expressed as a function of time.

The tissue nitrogen elimination in cubic centimeters, STPD, for the average of 33 subjects at the respective altitudes, amounted to 1,051, 816, 751, 679, and 645 cc. The average total oxygen inhaled by 33 subjects in 2 hours, expressed in liters of gas, STPD, amounted to 930, 621, 519, 406, and 268 liters at ground level and 8,000, 12,000, 18,000, and 22,000 ft., respectively. The average total air exhaled during this 2-hour period in liters of gas, STPD, amounted to 876, 595, 483, 371, and 253 liters at the respective altitudes.

These data show that during 2 hours' exposure to 38,000 ft. simulated altitude without benefit of denitrogenation, 16 of the 33 subjects, or 48.5%, suffered from bends before the end of the 2-hour period. After denitrogenation at ground level and then ascent to 38,000 ft. simulated altitude, 2 subjects, or 6.1%, suffered from bends. With denitrogenation at 8,000 ft., 2 subjects, or 6.1%, suffered from bends. With the 2-hour period of denitrogenation at 12,000 ft. followed by 2 hours' exposure to 38,000 ft., 5 subjects, or 15.1%, suffered from bends. Following denitrogenation at 18,000 ft., 3 subjects, or 9.1%, suffered from bends in the subsequent 2-hour stay at 38,000 ft. With denitrogenation for 2 hours at 22,000 ft. simulated altitude, 7 subjects, or 21.2%, suffered from symptoms of decompression sickness with subsequent exposure to 38,000 ft. simulated altitude.

Hemagglutination at Low Temperature: Research on Patients with Hepatic Cirrhosis. G. Silvestri and E. Picchio. Riforma med. 71:228-232 (March 2) 1957 (In Italian) [Naples]

The authors studied the hemagglutination at low temperatures in 18 patients with hepatic cirrhosis ascertained by means of needle biopsy. Marked dysproteinemia, evidenced by marked positive results obtained in tests of serum lability and by an increased sedimentation rate, was present in all patients. These findings showed no relationship to the appearance of hemagglutination at low temperature. Isoagglutination titers were higher than those of autoagglutination. Hemagglutination did not occur in 5 patients, and in another 5 it occurred in very low titers. Increased hemagglutination titers at low temperature (1:1,024) with concomitant increase of the gamma globulin fraction was observed in one patient. The authors point out that increase of the gamma globulin fraction is often present in patients with hepatic cirrhosis and therefore this observation does not prove that hemagglutination at low temperature is a specific biological phenomenon due to an antibody. The authors believe that the presence of hemagglutination is a valuable sign in determining the course of hemolytic anemia caused by cirrhosis of the liver.

PUBLIC HEALTH

Observations on Natural Poliovirus Infections in Immunized Children. H. M. Gelfand, J. P. Fox and D. R. LeBlanc. Am. J. Pub. Health 47:421-431 (April) 1957 [Albany, N. Y.]

Some 300 children who were lacking in immunity to one or more types of poliovirus and who were members of 118 southern Louisiana households which for several years had been under continuous observation in a study of the process of natural immunization, were given a primary course of Salk vaccine with 2 inoculations. The serologic response at 1 month after the second inoculation was determined by measuring the ability of the serums to inhibit the cytopathic effect of polioviruses. On an over-all basis, without reference to previous immunity, the 3 antigenic components of the vaccine were not equally effective, the type 2 component was the most antigenic and the type 3 was the least so. The response occurring *de novo* to a particular type of antigen was enhanced materially by the preexistence of heterotopic antibody.

In the first 7 months following vaccination the child members of the 118 households were closely observed for alimentary infections, and a total of 40 household episodes were detected. These observations, made after the vaccination, on the incidence of household episodes of infection, on the extent of spread of virus within the household, and on the frequency, duration, and amount of excretion of virus in the feces, were compared with similar observations made in the same study group in the period preceding the vaccination This comparison led to the conclusion that 2 doses of Salk vaccine did not materially influence the incidence or duration of alimentary infection or the amount of virus excreted in the feces Polioviruses depend on alimentary infections and not on infections of the central nervous system for their perpetuation in man The 2 essentials are (1) existing sources of infection in the form of intestinally infected persons discharging reasonably abundant virus in their feces, and (2) an adequate number of potential new sources of virus dissemination in the form of persons whose alimentary tracts are still fully susceptible to infection Hence booster inoculation also will fail to influence enteric infection and, as a corollary, extended use of killed virus vaccines will not result in the gradual elimination of polioviruses in the human population of areas in which vaccination is carried out

Problems Associated with Simultaneous Vaccination with BCG and Smallpox Vaccines H Møller Acta tuberc scandinav 33 143 156 (No 1-2) 1957 (In English) [Copenhagen]

In technically underdeveloped countries with shortage of medical personnel and difficulties of communication it is, from the practical point of view, often advantageous to carry out simultaneous or combined vaccinations by means of mobile teams The promoters of the idea of simultaneous and combined vaccinations were workers from Ecuador, Iran, and French overseas territories who have carried out field trials and reported satisfactory response and no complications In densely populated, highly industrialized countries with a comprehensive health service, experts advise against the procedure on theoretical grounds Serious general complications such as generalized vaccinia, postvaccinal encephalitis, and generalized BCG tuberculosis' are so rare that it will be impossible to ascertain any minor increase in their incidence resulting from a change of methods in vaccination Only a very great increase in incidence could be detected by control methods Because of their rarity, these complications are of little practical importance compared with the benefits of smallpox and BCG vaccinations in countries with high death rates from smallpox and primary tuberculosis To evaluate the results of simultaneous vaccination directly in terms of acquired, artificial immunity in a way that would satisfy medical statisticians will hardly be possible in the countries concerned Combined vaccination does not give any major advantage over simultaneous vaccination The main practical point is to be able to give several vaccinations at the same time A suggestion is made for a controled study of allergic reactions and local responses (including local complications) induced by simultaneous as compared with independent BCG and smallpox vaccination

Typhoid and Paratyphoid Carriers and Their Treatment M P Flynn J Irish M A 40 105-113 (April) 1957 [Dublin, Ireland]

The author reports on the use of different methods of treatment in 28 chronic typhoid carriers From 3 to 5% of patients with typhoid and 2% with paratyphoid B became chronic carriers Of the 27 fecal carriers 24 were women, the only urinary carrier was a man Middle-aged and elderly women constituted the majority of carriers Pathological gallbladders were found on x-ray examinations in about 85% of the carriers, and many had manifest symptoms of disease of this organ The gallbladder was the only site of persistence of infection in chronic fecal carriers, the organ acting as a test-tube containing infected bile It is likely that infection may persist in the uper bile passages Renal carriers frequently have an abnormality of the urinary ducts Their treatment is the elimination, usually surgical, of the abnormality

Cholecystography, to ascertain gallbladder function, and additional culture of duodenal contents were carried out Carriers with an apparently normal gallbladder or those in good general health or without evidence of renal or cardiovascular disease were given massive doses of penicillin with probenecid and/or a sulfonamide Cholecystectomy was the most successful method of treatment The feces of 5 of the 6 carriers operated on became negative for pathogens There was one operative death The gallbladder of this patient was almost completely sclerosed To accelerate and eventually to achieve the complete eradication of typhoid and paratyhoid, there should be no hesitation in advising operation for carriers who are average operative risks The dual purpose of the operation is to improve the carrier's own state of health and to safeguard the health of the carrier's relatives and of the population in general

Food Poisoning Due to Nicotinic Acid in Meat Report of an Outbreak E D Lyman, C J Potthoff and H P Jacobi Nebraska M J 42 243-245 (May) 1957 [Lincoln]

The authors describe an outbreak of food poisoning caused by nicotinic acid which was added to ground meat Of 145 persons consuming the meat 88 (60 7%) had typical symptoms of nicotinic acid poisoning such as flushing, especially in the face and neck, with heat and itching, sometimes accompanied by sweating and nausea, abdominal cramps, and acceleration of the pulse No harmful sequelae resulted, but the victims exhibited great anxiety and had a most unpleasant experience Nicotinic acid was added to prevent darkening of meat by inhibiting the conversion of the red myoglobin to the darker metmyoglobin This conversion involves the oxidation of the ferrous iron in the prosthetic group of myoglobin to the ferric state, the oxidation being facilitated by the succinoxidase enzyme system of the meat The practice of adding chemicals and compounds to food should be undertaken only with caution Preservation of perishable foods is best accomplished by cleanliness in processing followed by refrigeration during storage Heat may be used under certain circumstances

BOOK REVIEWS

Clinical Neuro Ophthalmology By Frank B Walsh M D, F R C S, D Sc, Associate Professor of Ophthalmology Johns Hopkins University, Baltimore Second edition Cloth $29 Pp 1294, with 441 illustrations Williams & Wilkins Company, Mount Royal and Guilford Aves Baltimore 2 1957

This new edition, coming 10 years after the first, is the most comprehensive work presently available to English speaking ophthalmologists New case histories have been added and obsolete concepts have been dropped The author makes liberal use of his wide personal experience Because of the decreasing infant mortality, the chapter on abnormalities and diseases of the eye and the central nervous system is of particular importance and warrants careful study On the other hand, because of the increasing life span, the chapter on degenerative, toxic, and metabolic diseases and vascular lesions demands study by the progressive ophthalmologist The chapter on toxic and metabolic diseases contains classical, concrete, and clear descriptions of diseases discussed in very few textbooks Whenever the original article on a particular subject is especially interesting, the author so states and recommends that it be read in its entirety This monumental work should be made available, either in private or public libraries, to the student of neurology and/or ophthalmology, to the instructor or professor of neurology or ophthalmology, and to the practicing ophthalmologist, neurologist, and neurosurgeon There is an index and bibliography

Perinatal Loss in Modern Obstetrics By Robert E L Nesbitt, Jr, M D Professor of Obstetrics and Gynecology, Albany Medical College, Albany, N Y Obstetrics & Gynecology series of monographs Edited by Claude E Heaton M D, Associate Professor of Obstetrics and Gynecology, New York University College of Medicine, New York Cloth $12 50 Pp 432, with 108 illustrations F A Davis Company, 1914-16 Cherry St, Philadelphia 3, 1957

'There is no medical problem today more challenging than this extravagance of nature in her quest for population recruitment Dr Nesbitt accepts this challenge, and his book should go far to combat the peril In discussing placental and uterine physiology, skillful clinical application of the researches of Reynolds, Wislocki, Dempsey, Thoms, and others makes fascinating reading The author, in earlier studies, has contributed much to this field, and no little credit can be ascribed to Dr Eastman for the able guidance given his protégé Anoxia causes more perinatal deaths than any other factor A relatively high incidence of this complication at Johns Hopkins Hospital is attributed by the author to the high proportion of nonwhite patients, who, in turn, help to reduce the incidence of erythroblastosis The various pathological features are well described and beautifully illustrated The nationwide significance of this disorder is indicated by the estimated 336,000 or more present victims of cerebral palsy alone To this stockpile an additional 11,000 are contributed annually, plus many others such as epileptics and mental defectives The author justifiably attributes many of these cases to intrauterine anoxia with resulting brain damage, although modern obstetrics has reduced the number ascribed to the severely traumatic deliveries in Little's original report True, defective embryological development will always characterize many of these, but much can be done by the attendant to reduce this high incidence in our future population Cognizance of the dangers of sedation and anesthesia, of oxytocia in labor, and of the intrinsic hazards of long labors, shock, and postmaturity will improve the score The premature infant, with increased capillary permeability and generally fragile tissues, is especially susceptible to brain damage

Retrolental fibroplasia, described initially by Terry in 1942, and later rightly attributed to overzealous therapy, is skillfully handled Patz's theory that normal retinal vascularization in the fetus depends on low oxygen tension in the choroidal vessels seems well substantiated Pulmonary hyaline-like membranes with resorption atelectasis and other lung lesions are well described and illustrated The many other problems encountered in fetal and neonatal deaths are described in detail, and then, in a masterful manner, the reader is presented with the means of prevention Mere recognition of the pathology would avail nothing In the evolution of the moral of each chapter the author pleads well for the prophylaxis for the future unborn millions Although this is not a book on therapy, the logical treatment and prevention of many of the disorders evolves in a simple and scientific manner This book should be read by everyone doing work in obstetrics—specialist, general practitioner, resident, or intern—and should be freely available in all maternity wards

Change and Dilemma in the Nursing Profession Studies of Nursing Services in a Large General Hospital Edited by Leonard Reissman and John H Rohrer Cloth $6 80 Pp 450, with illustrations G P Putnam's Sons, 210 Madison Ave, New York 16, McAinsh & Company, Ltd, Toronto, Canada, 1957

This report is the result of one of several research projects that have been financed in the past five years by the American Nurses Association It brings together the reports of two consecutive studies at Charity Hospital by the Urban Life Research Institute of Tulane University The first part deals with the four units of the hospital—medical, surgical, personnel infirmary, and central service The second part is devoted to the study of the premature infant center These two reports should be appraised as separate and independent They are not the work of any one person but rather the combined work of representatives of various disciplines Each person, guided by his particular interests and objectives, has studied the complex hos-

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated

pital environment, but always the role of the nurse—her functions, her relationship to other personnel and to patients, and her position within the hospital structure—has been the common denominator Most of the material that supports and documents the discussion presented in the body of the book is included in a series of appendixes Full statistical documentation, copies of schedules, questionnaires, and detailed descriptions of projective testing instruments appear in the appendixes

It is noteworthy that the conclusions of the various contributors, each operating within his separate sphere of interest, support and corroborate each other The image of the nurse emerges clearly in all the papers, and the dominant conflict between problems related to bedside care and problems of administration is discussed from every angle Various facets of the problem are described and possible solutions suggested The authors are correct in their suggestion that this volume can be read at several different levels of interest, depending on the orientation of the reader These papers report the findings in four studies on nursing services (their place, function, and personnel) in a large urban general hospital Information is also presented that is of more general interest to those connected with hospitals and the operation of hospitals for there are many instances in which the findings can be generalized to apply to hospitals other than the one studied Administrators, professional and nonprofessional hospital personnel, and even those of the general public who are interested in the subject can find valuable information in these studies A communality threads through each of these studies and documents significant changes in the nursing profession—changes of real import for hospital organization and for the community

The Metabolic Response to Neonatal Surgery By P P Rickham M S F R C S , D C H Consultant Paediatric Surgeon Royal Liverpool Children s Hospital Liverpool, England Cloth $5 Pp 93 with 12 illustrations Published for Commonwealth Fund by Harvard University Press Cambridge 38 Mass , Oxford University Press, Amen House, Warwick Sq , London E C 4, England 1957

This volume presents a detailed biochemical and physiological study of the metabolic changes that occurred in nine patients who were operated on during the neonatal period It summarizes over 3,500 chemical determinations made before and immediately after operation The postoperative period is studied until the patient has achieved some stability Emphasis is on quantitative measurement of the patient s intake (nutrition, fluids, electrolytes, and blood) and output (secretions, urine, stools, and perspiration) In spite of the small number of patients analyzed, the book represents a prodigious amount of work and is an excellent beginning toward providing information concerning metabolic changes associated with neonatal operations It is, in fact, a very good reference book for those interested in the problem An introductory summary of the available data on metabolic changes during operations in adults is provided, and these data are compared with information available about neonatal operative changes The analytical methods used for gathering the material in this book are described, and they are compared and contrasted with methods used for similar studies in adults Microchemical techniques are stressed As indicated by the author the volume has one unfortunate and unavoidable shortcoming Only a small number of cases have been studied Of necessity, therefore, the changes demonstrated can be regarded only as trends not as final observations However, these cases illustrate some of the weaknesses in neonatal physiology that should be considered in the preoperative and postoperative care of the infant They also help formulate a number of principles which the author believes are essential for improving neonatal operative mortality These are described in some detail, emphasis being laid on practical application of these principles in clinical cases

Urologic Injuries in Gynecology Including Vesicovaginal Fistula, Stress Incontinence and Ureteral Injuries By Henry C Falk M D , F A C S Director of Gynecology French Hospital New York Obstetrics & Gynecology series of monographs Edited by Claude E Heaton M D Association Professor of Obstetrics and Gynecology New York University College of Medicine, New York Cloth $7 50 Pp 265 with 97 illustrations F A Davis Company 1914-16 Cherry St Philadelphia 3, 1957

There was a time when childbirth was the principal cause of urinary tract damage with resulting fistulas A clearer understanding of the physiology and pathology of labor has served to provide more intelligent management of the parturient woman and a marked lessening of the injuries to the urogenital tract The small residue of injuries now remaining in this category are the product of poorly managed or badly neglected cases Progress in gynecologic surgery, however, has exacted its price in an increase in injuries to the urinary tract This book does not deal with urinary tract injuries associated with the radical and supraradical surgical treatment of pelvic malignancy It presents an excellent, practical, and detailed discussion of the principles and surgical management of urinary tract injuries associated with obstetric damage and the surgery of benign pelvic lesions Each condition is thoroughly analyzed as to cause and principles to be observed Excellent advice as to prevention is a valuable feature of the work Well-chosen illustrations show each successive step in the operations There is no skipping of intermediate steps, nothing is left to the imagination This valuable book belongs in the reference library of every gynecologist and urologist It will be consulted often and with profit in the management of these challenging cases which, fortunately, occur infrequently in an average practice

Industrial Toxicology By Lawrence T Fairhall Second edition Cloth $10 Pp 376 Williams & Wilkins Company, Mount Royal and Guilford Aves , Baltimore 2, 1957

In this new edition, published eight years after the first, Dr Fairhall maintains the format of the original edition and separates the subject matter into two main alphabetized groups inorganic substances and carbon compounds New additions to the first group include chlorine dioxide, decaborane, hydrazine, kaolin, ocher, and lithium The second group has been expanded to cover 46 additional compounds such as acetophenone, amyl acetate, butylamine, chlordane, malathion, methoxychlor, and parathion A brief digest of characteristics, industrial uses, toxicity, and methods of detection for each compound is presented A short list of pertinent references accompany each digest An added feature of the revised edition is an appendix that includes conversion tables for gases, end products of detoxification for 73 compounds, a table of the 1956 threshold limits adopted by the American Conference of Governmental Industrial Hygienists, and the comparative toxicities for 104 industrial and agricultural chemicals The great advances in chemical technology and the increasing accumulation of toxicological data on industrial chemicals are reflected in the revised edition As a reference book, it provides a quick digest of information on industrial poisons Because its orientation and emphasis is primarily directed to industrial hygienists, it may have only limited appeal to physicians outside of occupational medicine It is a welcome addition to the growing literature on industrial poisons

Signs and Symptoms Applied Pathologic Physiology and Clinical Interpretation Edited by Cyril Mitchell MacBryde A B, M D F A C P Associate Professor of Clinical Medicine Washington University School of Medicine St Louis Contributors Benjamin Alexander M D and others Third edition Cloth $12 Pp 973 with 197 illustrations J B Lippincott Company 227-231 S Sixth St, Philadelphia 5 2083 Guy St Montreal Canada, 1957

Although this book represents the combined efforts of 28 contributors, skillful editing has produced a smoothness and unity that is rare in medical books of this type The purpose of the book is to orient the student and physician as to the proper approach to diagnosis The book quite naturally begins with a chapter on history taking and is followed by several chapters on analysis of such symptoms as pain, headache, cough, dyspnea, cyanosis, and jaundice Three chapters not included in previous editions deal with growth and sex development, generalized vasospasm and arterial hypertension and lymphadenopathy and disorders of the lymphatic system At the end of each chapter a few well-selected references are listed Many tables and illustrations supplement the well-written text The index is complete The teaching experiences of the contributors and the editor are crystallized in this book so that it should be valuable to the medical student as well as to the practicing physician for ready reference

J A M A Clinical Abstract of Diagnosis and Treatment Published with approval of Board of Trustees American Medical Association Cloth $5 50 Pp 564 Intercontinental Medical Book Corporation, with Grune & Stratton, Inc, 381 Fourth Ave, New York 16, 1957

For the physician who finds it difficult to keep abreast of clinical medical developments, there must be a source of medical literature condensations that will allow him to learn of those articles he should read in full Such a source is found in the Medical Literature Abstracts section of THE JOURNAL of the American Medical Association The present compilation contains selected abstracts from THE JOURNAL that pertain most directly to diagnosis and treatment, arranged as they refer to a certain organ or disease This format integrates all contributions toward the patient and his illness rather than limiting new medical material to a specific specialty The digestive system, cardiovascular system, and reproductive system are representative chapter topics Other sections include poisonings and infections, and there are pertinent references to radiation, including isotopes, hazards, and protection The subject of drugs and drug reactions should be of interest to all practitioners There is an unusually comprehensive index Such a volume as this should be welcomed by every physician regardless of his specialty

Illustrated Medical and Health Encyclopedia Volumes 1-8 Edited by Morris Fishbein M D With collaboration of leading specialists in medicine and surgery Contains new entries and illustrations plus material from The Modern Home Medical Advisor and The Popular Medical Encyclopedia Cloth $19 50 Pp 1-269 277-541, 549-813, 821-1085 1093-1357, 1365-1629 1637-1901, 1909 2166 H S Stuttman Company, 404 Fourth Ave, New York 16, Copyright by Doubleday & Company, 575 Madison Ave, New York 22, 1957

This eight volume series on "medical information for the public' is an interesting, informative, and yet concise presentation of current knowledge on various medical topics It is not intended to advise people how to treat themselves but rather to supply basic information on health problems and the ways in which the medical profession can be helpful To supplement the presentation, there is a large number of illustrations which in themselves convey a wealth of helpful data The editor is known for his interest in medical writing, but he has called on the advice of experts to assist him in the compilation of these volumes Thus, about 30 men of medicine have pooled their information The topics are arranged in alphabetical order so that one may pass from a definition of the abdomen and information on abdominal pain to brief presentations on yaws, yellow fever, zinc, zygoma, and even zyme

A Text-Book of Surgical Pathology By Charles F W Illingworth C B E M D, Ch M Regius Professor of Surgery, University of Glasgow, Glasgow, and Bruce M Dick, M B, F R C S, Regional Consultant in Thoracic Surgery, Western Region, Busby, Scotland Seventh edition Cloth $14 Pp 730, with 322 illustrations Little, Brown & Company, 34 Beacon St Boston 6, J & A Churchill Ltd, 104 Gloucester Pl, Portman Sq, *London*, W 1, *England*, 1956

This new edition is excellent and up to date As stated in the preface, sections discussing some conditions, particularly those that have been controlled largely by antibiotics and no longer present a problem, have been abridged Sections discussing conditions such as water and electrolyte imbalance, hypothermia, metabolic disorders due to trauma, endocrine dysfunction, cancer, and portal hypertension, and the use of radioisotopes have been added or elaborated on The style is concise and excellent for students, interns, and residents The many illustrations are well done The only defect is that the bibliography is limited almost entirely to British sources The book would be a valuable addition to any surgeon's library

Whitla's Dictionary of Medical Treatment By R S Allison V R D, M D, F R C P, Lecturer in Neurology, Queens University, Belfast, T H Crozier, M D, B Sc, F R C P, and 26 contributors Ninth edition Cloth $10 50 Pp 854, with illustrations Williams & Wilkins Company, Mount Royal and Guilford Aves, Baltimore 2, Bailliere, Tindall & Cox, 7-8 Henrietta St, Covent Garden, London W C 2, England, 1957

Therapeutics, although universal in scope, is nevertheless influenced greatly by the country in which it is practiced This compendium of numerous therapeutic procedures, contributed by 28 authorities, presents primarily the British viewpoint Although up-to-date and of great value for the British general practitioner, it has limited usefulness for the physicians of other countries except for comparative reference purposes The book is self-indexing in that each subject is presented alphabetically A comprehensive cross index is also included The text is clear The subjects are treated concisely with sufficient information for initiating interest but not enough detail for complete coverage

Clinical Use of Radioisotopes A Manual of Technique Edited by Theodore Fields M S, F A C R, Assistant Director Radioisotopes Service, Veterans Administration Hospital Hines Ill, and Lindon Seed M D, Clinical Associate Professor of Surgery, University of Illinois College of Medicine Chicago Cloth $9 50 Pp 455 with 71 illustrations Year Book Publishers, Inc, 200 E Illinois St, Chicago 11, 1957

Only those procedures that the editors considered to be currently accepted and most representative of the various clinical procedures used are described and discussed in this manual Individual chapters were contributed by well-qualified experts The manual is divided into sections dealing with routine clinical diagnostic tests, routine clinical therapeutic techniques, planning and operating the radioisotope laboratory, and radiation safety It is well written lucidly presented, and should be especially useful to those who have had some experience with radioisotopes

The Family Book of Child Care By Niles Newton Ph D Assistant Professor of Psychiatry, School of Medicine, University of Mississippi, Jackson With editorial collaboration of Paul Gyorgy M D Professor of Pediatrics School of Medicine University of Pennsylvania Philadelphia Irwin M Marcus M D Clinical Associate Professor of Psychiatry and Director of Family Study Unit School of Medicine Tulane University New Orleans and Thaddeus L Montgomery, M D Professor of Obstetrics and Gynecology Jefferson Medical College Philadelphia Cloth $4 95 Pp 477 with illustrations by Ora H Harris Harper & Brothers, 49 E 33rd St, New York 16 1957

This book contains a vast amount of useful information for mothers, fathers, social workers, nurses, and others directly concerned with infant and child care The book is well written and stresses the psychological aspects but does not neglect the medical side of child rearing The importance attached to breast feeding is evidenced by the 24 pages covering this as against five pages devoted to bottle feeding Demand feeding is stressed The authors recommend early introduction of cup feedings Much space is devoted to child and family relationship The appendix contains a list of organizations helpful to parents who want specialized information and an excellent selective book list for further reading Parents, prospective parents, pediatricians, and others intimately concerned with child care should find this book of much value

Hemorrhagic Diseases By Armand J Quick Ph D M D Professor of Biochemistry, Marquette University School of Medicine Milwaukee [Second edition] Cloth $9 50 Pp 451 with 37 illustrations Lea & Febiger, 600 S Washington Sq Philadelphia 6, 1957

This monograph is intended to replace an earlier edition that had become so out-of-date that essentially a new book had to be written For those especially interested in the field of coagulation this is a valuable treatise It discusses the developments in this field in the course of the last 20 or more years as seen by a man who became interested in the field at the beginning of the modern era and has contributed greatly to our present knowledge of coagulation and hemorrhagic diseases Against the background of the history of this subject, the developments in the last several decades are outlined and interpreted The book should also prove useful to nonspecialists, since it affords an up-to date account of the various diseases one encounters and discusses their differentiation and management in a concise and clear manner In addition, almost 100 pages are devoted to laboratory methods that the author has found helpful As with most books, it is possible to find matters for minor criticism Thus, for example, the problem of terminology which has so plagued the field of coagulation is handled chiefly by ignoring it One can find such terms as accelerator globulin, 'proconvertin, and parahemophilia' in the index, but they are ignored in the text It would be useful if the reader were given the terms used by others Again, Dr Quick uses the terms pseudohemophilia A and pseudohemophilia B apparently without concern for the fact that they are not descriptive and are even misleading, according to the definitions given, the disorders to which they refer in no way resemble hemophilia In matters of technique, one is surprised to see that a spring lancet is recommended for use in the measurement of bleeding time, ignoring the possibility of transmitting infectious hepatitis by the use of the same instrument in patient after patient Despite these minor faults the book is well written, the style is clear, and the treatise is well worth having

Jordan's Tropical Hygiene and Sanitation By W Wilkie, Instructor in Hygiene School of Hygiene, Uganda Bailliere's Elementary Tropical Handbook Third edition Cloth $5 Pp 408 with 122 illustrations Bailliere Tindall & Cox 7-8 Henrietta St Covent Garden London, W C 2 England [Williams & Wilkins Company Mount Royal and Guilford Aves Baltimore 2] 1956

This handy book should be of special interest to those who are concerned with hygiene and sanitation in tropical areas However, much of the information can be used in more temperate regions, and for this reason the volume should be useful as a quick reference source It is not as complete as some of the larger textbooks, but then, presumably, it is not intended to be

QUERIES AND MINOR NOTES

TREATMENT OF ASIATIC INFLUENZA

To the Editor —*What is the best possible treatment of Asiatic influenza, at least in the initial stage? Inasmuch as no vaccine is available here, what could be done to control symptoms?*

Karl Pollak, M D , Addis Ababa, Ethiopia

Answer —There is no specific therapy for any type of influenza Treatment is therefore directed toward control of symptoms Sneezing, coughing, coryza, muscular aches and pains, chills, headache, sore throat, prostration and convalescent debility are the general presenting problems Depending on the predominant symptoms, some relief, transient though it might be, may be offered to the patient Analgesics, antipyretics, antitussives, antihistamines, antibiotics, and expectorants constitute the armamentarium Supportive measures consist of bed rest, light diet, and fluids as needed

Chemotherapy or treatment with antibiotics should not be used in the absence of establishing or developing bacterial complications Older patients and those with disabling systemic disease may require prophylactic use of chemotherapy or antibiotics Active immunization with currently available vaccines achieves a substantial reduction in the incidence of influenza, provided that the prevailing strain of virus matches closely the antigenic components of the vaccine used and the vaccine is given early enough to be effective

PAIN AT NIGHT IN KNEE

To the Editor —*A 60-year-old man has been troubled with pain on the medial aspect of both knees for the past two years The pain has come on only when in bed but has been severe enough to awaken him nearly every night There have been no muscle cramps Physical examination reveals adequate circulation and no abnormal neurological signs Several x-ray studies have shown nothing abnormal except a loose body posteriorly in the joint space of the left knee Is there a possible explanation, and what additional studies should be done?*

James P Baker, M D ,
White Sulphur Springs, W Va

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —This inquiry does not contain sufficient information to offer more than an outline as to what further should be done It is obvious that posture and sleep are directly related to the experience, if these are the facts The first step would be to determine whether there is any local factor responsible for the severe pain at night, that is, in view of the fact that the x-ray studies have shown no abnormality, whether the patient s sleeping posture would, if on the side, cause compression of the knees together in the event that he did not have sufficient fatty tissue to prevent direct pressure during a period of relaxation

Pain in this area may be referred due to pathology in the hip joints, and this area should be studied The Patrick sign would be important to elicit, and should this prove to be absent, then the lumbar spine might be considered as a possibility for this bilateral pain The pain and the incidence of bilaterality do not indicate to this consultant disk involvement but may, in periods of relaxation, involve some of the roots of exit, and, if the area is correctly localized, one would suspect the fourth lumbar root Root pain usually has a burning quality, and this is not stated in the inquiry

The following test might prove to be of some benefit or at least suggest the possible diagnosis if the condition is in the lumbar spine The patient stands with feet together and knees locked back in a straight upright position He is then requested to bend forward If the pain is produced by bending forward at approximately a 30-to-45 degree angle with the knees straight or by stretching a sciatic nerve, a disk or root involvement can be suspected If, however, when the patient flexes the knees in a semisquatting position and bends forward, should he be able to bend farther than was the case in the first instance, the sciatic and nerve distribution might be thus detected If, when the patient squats, the bending forward is arrested at the same point because of the onset of pain, a vertebral or structural spinal involvement can be suspected

In either event, stereoscopic x-rays of the lumbar area, centering the film around the fourth lumbar vertebra and its roots of exit, taking both lateral and anterior-posterior stereoscopic exposures, may disclose lipping of the vertebral edges or some distinct and localizing factor which might become operative during the relaxed period of posture in sleep

Answer —There is insufficient information about this patient other than his age and the complaint of pain on the medial aspect of both knees Since local examination and roentgen studies have revealed no pathology in the areas of pain, one might consider studying the spinal cord and cauda equina X-rays of the thoracic and lumbar spine seem indicated Further information may be gained from the performance of a lumbar puncture To make this study complete, the puncture would best be done at a low interspace, and a Queckenstedt test should be performed Analysis of the cerebrospinal fluid should certainly include a total protein determination Further information would be derived from performing a myelogram at the same time At this point, no explanation for the patient's complaint is apparent

---

The answers here published have been prepared by competent authorities They do not, however represent the opinions of any medical or other organization unless specifically so stated in the reply Anonymous communications and queries on postal cards cannot be answered Every letter must contain the writer s name and address but these will be omitted on request

MICROMETHOD DETERMINATION OF BILIRUBIN IN ERYTHROBLASTOSIS

To the Editor —*In the proper care of an infant with erythroblastosis fetalis, careful attention should be paid to the bilirubin level of the blood At the present time, most determinations of this level require a vein puncture and the removal of 5 to 10 cc of blood from the infant This is especially true in the smaller local hospitals in which the more inexpensive photometers are used Not only does the vein puncture require considerable effort and time, with considerable blood being drawn, but it can be rather traumatic to the infant Is there any accepted micromethod of bilirubin determination which can be used in the smaller hospitals and which can deal with a small enough quantity of blood so as to require only a heel prick or other puncture? The method could have a margin of error of ± 2 mg per 100 cc and still be of great use in the screening of these infants Please supply information as to the exact type of equipment needed*

Graham A Barden Jr, M D, New Bern, N C

Answer —Determination of bilirubin in serum (micromethod) is based on the principle of the quantitative Van den Bergh test by means of electrophotometry In carrying out the procedure, the steps are as follows 1 In a test tube place 0 5 ml of serum diluted with 9 5 ml of distilled water (if blood is drawn from the umbilical cord, it should be centrifuged and 0 5 ml of serum removed) 2 Into a colorimeter tube add 6 ml of methyl alcohol, 1 ml of freshly prepared diazo reagent, and 5 ml of diluted serum Hemolysis should be avoided, if possible 3 Into a colorimeter tube labeled blank' transfer 6 ml of methyl alcohol, 1 ml of diazo blank, and 5 ml of diluted serum 4 Invert the tube several times, keep it at room temperature for 30 minutes, and read it in the colorimeter If bubbles form, dislodge them by tapping the tube gently on a table 5 If an Evelyn colorimeter is used, filter no 540 should be used If a Coleman spectrophotometer is used, filter no 550 should be used Place the blank in the instrument and set the galvanometer to read 100 Insert the sample tube and record the galvanometer reading If the reading is below 10, add 12 ml of 50% methyl alcohol to each tube and repeat the readings, results obtained are multiplied by 2

A calibration can be made, and the concentration of serum bilirubin is expressed in milligrams per 100 ml The calibration curve can be prepared by placing 1 2, 4, 6, and 8 ml of standard bilirubin solution in a series of tubes, each containing 1 ml of diazo reagent, and adding ethyl alcohol to each tube to make a final volume of 10 ml A blank tube is prepared by diluting 1 ml of diazo blank with 9 ml of ethyl alcohol The bilirubin concentrations in these standards equal 2, 5, 10, 15, and 20 mg of bilirubin per 100 ml of serum

So far as interpretations are concerned, the average normal level of bilirubin in serum in children and in adults is between 0 25 and 0 75 mg (average, 0 5 mg per 100 ml) Between the upper limit of normal and 2 mg per 100 ml is the zone of latent jaundice, above 2 mg is the zone associated with clinical jaundice According to Dr H J Behrendt (Diagnostic Tests for Infants and Children, New York, Interscience Publishers, Inc, 1949), abnormally high bilirubin levels cannot be applied to newborn infants The majority develop physiological hyperbilirubinemia with and without concomitant jaundice Hyperbilirubinemia attains its highest degree between the second and fifth days of life Davidson, Merritt, and Weech (*Am J Dis Child* 61 958-980 [May] 1941) have demonstrated that in young infants there is no critical serum bilirubin level as regards visible jaundice Infants do not develop clinical jaundice during the neonatal period, the majority showing no icterus until serum bilirubin is approximately 4-5 mg per 100 ml There is no consistent correlation between the appearance and degree of jaundice and the intensity of hyperbilirubinemia

TONSILLECTOMY IN PRESENCE OF HEMOPHILIA

To the Editor —*A 12-year-old boy with hemophilia has recurrent tonsillitis and is in need of a tonsillectomy Is there any type of therapy which would enable this patient to withstand this procedure successfully?*

Donald I Purcell, M D, Paragould, Ark

Answer —Surgery in cases of hemophilia is always hazardous, and, therefore, one hesitates to recommend an elective operation In an emergency, 500 ml of fresh or fresh-frozen plasma should be given immediately before the operation and another 250 ml several hours later The need of further transfusions is best determined by the clinical course The effect of the transfusion should be determined by the prothrombin consumption time Whole blood generally should not be given unless the hemoglobin level drops below 8 Gm per 100 ml of blood

TONSILLECTOMY IN PATIENTS WITH CONGENITAL CORTICAL HYPEROSTOSIS

To the Editor —*Please advise as to doing a tonsillectomy on a small boy with congenital cortical hyperostosis (Caffeys syndrome)*

Ralph A Lundeberg, M D Griffith, Ind

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —Congenital cortical hyperostosis is a disorder affecting the skeleton and some of its adjacent fascias and muscles The cause is unknown and the pathogenesis obscure Many patients have severe and protracted fever, and in most the erythrocyte sedimentation rate is increased there is also increased phosphatase activity of the blood serum during the active phases of the swelling and fever The average age of onset is 9 weeks The bone marrow is characteristically fibrotic without abnormal cells Neither bacteria nor viruses have been cultured from the affected tissues, nor have serologic tests disclosed reactions to infections Intimal proliferation in the small arteries has been reported in the region of the bone and fascial lesions The uneven, protracted clinical course of the disease, with unpredictable remissions and relapses, is one of the most characteristic features and one which makes evaluation of therapeutic agents uncertain

If tonsillectomy is definitely indicated, the usual precautions should be taken preoperatively, such as a chest x-ray and physical examination to exclude possible pleural effusion, in addition, consideration should be given to the presence of thrombocytopenia because of the fibrinous replacement of bone marrow Hemorrhagic studies should include platelet count, tourniquet test, and determinations of bleeding, coagulation, and prothrombin times

Answer —Unless the *indication for tonsillectomy is* extremely urgent, it would be unwise to carry out the procedure while the patient has congenital cortical hyperostosis, for during the acute phase of the disorder he may show such signs of illness as malaise, fever, anorexia, and leukocytosis Once the acute phase has passed, and during the period in which the osseous and periosteal lesions are subsiding, or after they have disappeared, tonsillectomy should offer little more risk than in the case of any young patient It is probable that few, if any, tonsillectomies have been performed on babies during the acute phase of the disease, and consequently there would be little, if any, information regarding complications that might follow such a procedure

HYPERBILIRUBINEMIA

To the Editor —*A 42-year-old man in good health gave blood as a volunteer donor, and the serum was observed to be tinged For that reason a bilirubin test was done and revealed 0 2 mg per 100 cc direct and 2 mg total A cephalin flocculation test was then done and revealed 1+ after 24 hours and 2+ after 48 hours Physical examination was essentially negative, and the hemoglobin level was found to be 16 Gm per 100 cc This man is a roofer He has very rarely handled tar but almost daily uses hydrochloric acid Is it possible that the hydrochloric acid is responsible? What further diagnostic tests should be performed?*

Ellis M Markell, M D , Harrison, N Y

Answer —Hydrochloric acid is neither a hepatotoxic nor an hemolytic agent and, therefore, could not be held responsible for this individual's hyperbilirubinemia Since the possibility of viral hepatitis exists, such individuals should not be used as blood donors A thymol turbidity and flocculation test may be positive in spite of a nearly negative cephalin flocculation test Therefore, these tests should also be done A sulfobromophtalein test would, likewise, help to determine whether there is parenchymatous liver disease

Because of the low (0 2 mg per 100 cc) one-minute or direct-reacting bilirubin value, it is unlikely that the hyperbilirubinemia is due to extrahepatic biliary obstruction or infiltrative lesions of the liver The urine should be tested for bilirubin and urobilinogen The presence of urobilinogen may indicate either parenchymatous liver disease or hemolysis In spite of the high hemoglobin level a compensated hemolytic process may exist The absence of reticulocytosis would rule it out If all these tests are negative and a mild hyperbilirubinemia persists, the patient may belong to the group with congenital or familial nonhemolytic jaundice or idiopathic hepatic dysfunction

HEART MASSAGE IN A NEWBORN INFANT

To the Editor —*Because of uterine inertia, a cesarean section with the aid of spinal anesthesia was performed on a 36-year-old woman The infant, weighing about 11 5 lb (5,216 Gm), made no effort to breathe on delivery, despite the usual resuscitative efforts, i e , suction of the nasopharynx, aspiration of the stomach, external stimulation, and administration of oxygen through the Kreiselman resuscitator Heart beat, which seemed feeble on delivery, was no longer palpable or audible Intracardiac therapy with epinephrine was employed, and oxygen was administered with an endotracheal tube, inserted under direct vision under positive pressure Because no heart beat could be obtained, the left side of the chest was opened There was no bleeding, and the heart was at a standstill After three or four massaging efforts, the heart was felt to beat vigorously Respiratory efforts started after five minutes of administration of oxygen intermittently under positive pressure The chest was closed with an underwater seal, and the baby left the operating room in good condition Please supply information as to whether the above is a standard procedure in circumstances such as described Have there been many such incidents reported?*

M Halperin, M D , East Stroudsburg, Pa

Answer —As far as is known, the operation described in the query is the first one reported on a newborn baby When definitely indicated, this type of operation should be done Information about operations of the kind described is fully given in an article by Thorek (*J Internat Coll Surgeons* 22 134, 1954) and also in a book by Bailey (Emergency Surgery, Baltimore, Williams & Wilkins Company, 1952)

REBREATHING RESUSCITATOR FOLLOWING INHALATION OF CHLORINATED HYDROCARBONS

To the Editor —*The police-department ambulances in our city have recently been provided with the Western Reserve Inhalator and Resuscitator It is probable that a soda-lime cannister assembly will be used as part of the unit Conceivably, this equipment might be needed in cases of industrial nature where there has been inhalation of chlorinated hydrocarbon material Is there any danger that soda lime might break down chlorinated hydrocarbons, such as carbon tetrachloride or tetrachloroethylene, which would be present in the rebreathing bag and produce an irritant or poisonous product, such as phosgene? Are there any other situations in which use of such equipment by persons with only first-aid training might have unrecognized hazards?*

Harry D Baernstein Jr , M D , Racine, Wis

Answer —The Western Reserve Inhalator and Resuscitator is a pocket-size unit employing thumb size oxygen cylinders which are readily replaceable The soda-lime absorption unit is common to many rebreathing types of inhalators, so that this reply is somewhat general The purpose of the soda lime is to remove the carbon dioxide from the exhaled air At the temperature involved, it is not known whether carbon tetrachloride or closely related chlorinated hydrocarbons are modified by soda lime or whether the chlorinated hydrocarbons are absorbed or adsorbed as such The assumption is that the chlorinated hydrocarbons are rebreathed Considering the volume of exhaled carbon tetrachloride or such in a given period, it is unlikely that any evil consequences would arise, even though traces of phosgene were produced Some merit might attend the question of the preferability of an open resuscitator system in order that the exhaled chlorinated hydrocarbons might not be rebreathed

GALLBLADDER DISEASE AND CARDIAC IRREGULARITIES

To the Editor —*A patient, 65 years of age, for the past three years has had bouts of diarrhea accompanied by cramps and rectal tenesmus Also present is recurrent intermittent auricular fibrillation and at times dropped beats A thorough physical and laboratory examination is negative, except for a large stone in the gallbladder No material has been found in the literature which would incriminate the gallbladder in these two conditions Moreover, the patient has no gallbladder symptoms per se, and the gallbladder shows good functioning Is it indicated that the gallbladder should be removed surgically for the relief of auricular fibrillation and the recurrence of bouts of diarrhea?* *M D Florida*

Answer —There has been a good deal of speculation in the past about the relation of gallbladder disease to disturbances of the heart and disorders of the digestive tract Attacks of cholecystitis have been, at times, mistaken for heart attacks, and so-called heart attacks have been relieved by removal of the gallbladder In an individual of 65, a variety of conditions could be responsible for the auricular fibrillation There is no evidence that a symptomless gallstone would play a part in its origin

Cholecystitis may be a factor in causing digestive upsets and particularly periodic loose stools Cholecystitis may be associated with an achlorhydria, and this could be a factor in the diarrhea of an occasional individual Cholecystectomy might be considered in an individual of 65 who has an asymptomatic gallbladder only from the standpoint of protection of the liver and in the hope of improving digestive disturbances, but hardly in the hope of improving the cardiac status

X-RAY THERAPY FOR VERRUCA PLANTARIS

To the Editor —*What is the present prevalent opinion regarding the use of 'deep' x-ray therapy for verruca plantaris (plantar warts)? Is it felt that such therapy is more warranted if other methods have failed?* *Harrison R Hines, M D, Pittsburg, Calif*

Answer —There is considerable variation of opinion as to the advisability of x-ray therapy for verruca plantaris Deep therapy in the sense of penetrating short-wave radiation is not advisable, since such plantar warts are entirely in the epidermis The quality of radiation used is ordinarily of the "superficial" type, i e, with a half-value layer of 1-2 mm Al It is believed that there has been a steady trend away from routine x-ray therapy of verruca plantaris in the past decade The rates of cure reported vary considerably, and all such results include a psychotherapeutic component which, in the case of warts, is large with any method of treatment Under no circumstances should irradiation be given to the point of even slight atrophic changes, on pressure sites this may eventually lead to a painful hyperkeratotic scar Larger doses have at times in the past produced severe late x-ray changes and ulceration and have sometimes necessitated extensive plastic repair Most observers at the present time regard a total dose of 1,000 r, measured in air, sharply screened to the individual wart, as the maximum allowable dose Some clinicians, including this consultant, have discontinued x-ray therapy entirely for plantar warts, preferring to rely on methods of treatment which are entirely safe and in which there is little or no possibility of producing a painful scar that is often more disabling and painful than the original wart Possibly the most popular current method of treatment is the application of 20% podophyllin in compound tincture of benzoin to the wart, and then covering it with adhesive tape to induce some degree of maceration This application is repeated at intervals of 48 to 72 hours by the patient The treatment must sometimes be continued for periods of as long as two or three months, but results have been reasonably satisfactory in at least 85% of the cases There are, of course, many alternate chemotherapeutic methods Full-thickness surgical excision or deep electrocoagulation and curettage of warts frequently produce considerable disability after operation and almost inevitably result in a more or less painful scar on sites of pressure

ACCIDENTAL INGESTION OF WARFARIN

To the Editor —*Could the accidental ingestion of warfarin sodium be damaging to an individual? About how much would have to be ingested before symptoms occurred, and when would one expect to observe evidence of intoxication? What is the treatment?* *M D, Illinois*

Answer —The accidental ingestion of warfarin sodium, if taken in excessive amounts, could be most damaging if not catastrophic The effects would be related to the quantity taken This water-soluble coumarin derivative is readily absorbed, and the prothrombinopenic and other alterations in the clotting mechanism are rapidly induced If the quantity exceeds that generally recommended for the preparation (100 mg for the first day and 25 mg approximately every two days thereafter), dangerously low levels of plasma prothrombin and proconvertin will ensue within approximately 48 hours, and hemorrhagic phenomena, characterized by ecchymosis, or mucosal bleeding from the nose, gastrointestinal tract, urinary tract, etc, as well as into other areas of the body, may be expected Most effective treatment of overexposure to the coumarin derivatives includes (1) prompt transfusion with blood or plasma and (2) immediate administration of vitamin K_1, parenterally or orally

PREGNANCY AFTER PELVIC FLOOR REPAIR

To THE EDITOR —*In gynecologic practice one occasionally sees young women who have had children having cystocele and rectocele which cause intolerable symptoms Naturally, if these conditions are corrected surgically, a future pregnancy would not be indicated A patient who has undergone perineorrhaphy and becomes pregnant would certainly be a candidate for cesarean section With the assumption that cesarean section was elected by the patient and that the physician feared a return of her former distress, what would be the position of gynecologists as to tubal ligation at this time, the patient's consent being assumed?*

Percy J Tuthill, M D , Greenport, N Y

ANSWER —It cannot be agreed that pregnancy is contraindicated after a pelvic floor repair A deep mediolateral episiotomy performed as soon as the baby s head reaches the pelvic floor will prevent, to a great extent, a breakdown of the repair Apropos the case cited, the maternal and fetal morbidity and mortality after cesarean section though admittedly low are much greater than those which follow vaginal delivery including the possibility of recurrence of pelvic floor relaxation As a general rule young women should not be sterilized except for medical reasons A pelvic floor repair, per se is not an indication for cesarean section or for tubal ligation

HARMFUL EFFECTS OF DAILY ENEMA

To THE EDITOR —*Reference is made to the query, Harmful Effects of Daily Enema appearing in the Queries and Minor Notes section of* THE JOURNAL, *May 25, 1957, page 508 Dunning and Plum* (Am J Med **20** *789, 1956, and* Am J M Sc **233** *387, 1957) have reported that prolonged use of enemas in patients with cord lesions or with restricted potassium intake may result in the increased gastrointestinal excretion of potassium to a degree sufficient to induce severe hypokalemia*

George X Trimble, M D
1044 Belmont Ave
Youngstown 4, Ohio

The above comment was referred to the consultant who answered the original query, and his reply follows —ED

To THE EDITOR —*The possibilities of inducing hypokalemia by the prolonged use of plain water enemas are of clinical significance Loss of potassium may and does follow even the short-term presurgical preparation of the colon, as alluded to by Roberts and associates* (S Clin North America **35** *1189, 1955) and emphasized by Turell* (S Clin North America **35** *1211, 1955) because it is not generally appreciated*

Until April of this year this consultant did not know whether hypokalemia might follow the use of concentrated sodium phosphate enemas However, at the annual meeting of the American Proctologic Society held in New Orleans in April, Drs Flentie and Cherkin, during a symposium on colon physiology, stated that no loss of potassium followed the use of concentrated sodium salt enemas Confirmation of their results is necessary Parenthetically, they noted the figure of 4-135 mEq of unexpelled salt with the experimental concentrated salt enema return and warned that 'such retention may be undesirable in patients on a low-sodium regimen"—a point that is stressed in the original reply

TREATMENT OF GIARDIA LAMBLIA INFECTION

To THE EDITOR —*I wish to draw your attention to an error in the dosage of Acranil prescribed for the treatment of Giardia lamblia infection in the Queries and Minor Notes section of* THE JOURNAL *for June 29, 1957, page 1041 The first consultant recommended Acranil, 0 25 Gm a day (one-half tablet) for children under 2 years of age and 3 (0 5 Gm) tablets a day for patients over 10 years of age*

Acranil hydrochloride has the same range of toxicity as Atabrine hydrochloride, and therefore it would be toxic at the prescribed dose levels According to the files of the Sterling-Winthrop Research Institute, the acute oral LD$_{50}$ *of Acranil for mice is 780 ±70 mg per kilogram and that of Atabrine (Barlow and others* J Lab & Clin Med **30** *20, 1945) is 706± 16 mg per kilogram The dose of Acranil for the treament of giardiasis as originally used by me* (Am J Trop Med **25** *441 1945) was as follows*

Children 3 to 6 years old—1 tablet (0 1 Gm) daily for five days

Children 7 to 12 years old—1 tablet (0 1 Gm) twice daily for five days

Children above 13 years of age and for adults—1 tablet (0 1 Gm) three times daily for five days

To the best of my knowledge Acranil is not commercially available in this country It has been supplied in Germany in 100-mg tablets (not 0 5 Gm tablets) Your consultant suggested the equivalent of 15 tablets a day (of the 0 1-Gm dosage) for five days for patients over 10 years of age In my experience a single dose of 6 to 8 (0 1-Gm) tablets (administered for tapeworm treatment) caused a high incidence of violent vomiting and near collapse In view of the cumulative property of Atabrine and related acridines, I feel certain that 15 tablets a day would be unsafe

D A Berberian, M D
Sterling-Winthrop Research Institute
Rensselaer, N Y

The above comment was referred to the consultant who answered the original query, and his reply follows —ED

To THE EDITOR —*Since the original question submitted indicated a resistive case in which two courses of Atabrine' were tried, the use of Acranil was suggested Craig and Faust s "Clinical Parasitology" (ed 5, Philadelphia, Lea & Febiger, 1951, p 147) gives the suggested dose of Acranil, as does Manson's 'Tropical Diseases' (ed 14, Baltimore, Williams & Wilkins Company, 1954, p 540) Acranil is a derivative of an acridine compound The acridine dyes have been used in medicine for many years, and according to the standard books on pharmacology these products are of established low toxicity If 0 5-Gm tablets are not available, a pharmacy can put up the preparation in the desired form and dose*

THE SEROLOGIC DIAGNOSIS OF RHEUMATOID ARTHRITIS

Norman O. Rothermich, M.D.
and
Vol K. Philips, M.D., Columbus, Ohio

• A new test, involving the use of a suspension of latex particles, was applied to 1,606 samples of serum from 907 patients whose clinical diagnoses, whether of rheumatic disease or otherwise, had been established. The latex particles in stock suspension had a fairly uniform mean diameter of 1.17 microns. For the test they were mixed with borate buffer and gamma globulin. When the serum to be tested is added to this mixture it may or may not cause aggregation of the particles. A positive test is indicated by discernible aggregation, which can be read with the naked eye. Of 291 patients who met the clinical criteria for the diagnosis of rheumatoid arthritis, 245 (84.2%) showed positive latex fixation tests; the 46 instances of false-negative reactions have been studied. Of 414 patients with rheumatic disease other than rheumatoid arthritis, 399 (96.3%) gave negative latex fixation reactions; the 15 false-positive reactions have likewise been studied. The test was as reliable as are the various sheep cell agglutination tests now used for serologic detection of rheumatoid arthritis, and it had the advantage of being simple, very inexpensive, fast, and clinically useful.

Despite some opinions to the contrary, the diagnosis of rheumatoid arthritis in clinical practice remains very often a perplexing and vexing problem. The truth of this statement was well illustrated when the American Rheumatism Association found it necessary to set up a committee on diagnostic criteria. This committee, headed by Dr. Marion Ropes of Boston, carried out its very difficult assignment in a most thorough and commendable manner, but still felt compelled to list a set of 11 criteria from which any 5 would permit a "definite diagnosis."[1] Less certain diagnoses were permitted with less criteria, and the categories of "probable rheumatoid arthritis" and "possible rheumatoid arthritis" reveal rather pathetically a weakness and lack of certainty in the diagnosis of rheumatic diseases generally and rheumatoid arthritis specifically. The committee's efforts have already been recognized to be of inestimable value but leave no doubt of the great need for laboratory diagnostic aids which are simple, practicable, and reliably accurate to a statistically significant degree.

The erythrocyte-sedimentation rate is a time-honored and well-established laboratory aid in the diagnosis of rheumatoid arthritis, but it is wholly lacking in specificity. More recently other substances (generally referred to as acute phase reactants) such as the nonglucosamine polysaccharides and hexosamines have been reported to be elevated in rheumatoid arthritis, but these too are nonspecific, being increased in rheumatic fever and other allied diseases.[2] Probing into the area of serologic reactions led to the development of the antistreptolysin titer, which is notoriously negative in rheumatoid arthritis, the hemolytic Streptococcus agglutination test, which is not practicable and is largely lacking in any degree of specificity, and more recently the sensitized sheep cell agglutination reaction.[3] Extensive studies of this last named have led to an awareness of the existence of a specific factor in the serum of patients with rheumatoid arthritis.[3a] The refinements of the sensitized sheep cell agglutination test have decreased the percentage of false-negative results but proportionately increased the percentage of false-positive findings. The demonstration of an inhibitor of this hemagglutination by the Ziff group [3c] as well as by Heller and associates [3b] has materially enhanced the specificity and sensitivity of this test. Nevertheless, the test is extremely cumbersome, expensive, and completely impractical for routine use as a diagnostic aid in clinical rheumatology.

At the meeting of the American Rheumatism Association in Chicago in June, 1956, Plotz and Singer[4] reported the ingenious adaptation of polystyrene latex particles, which are of a remarkable constancy in cali-

---

From the Division of Rheumatic Diseases, Department of Medicine, Ohio State University Health Center.

ber, to an agglutination procedure, this appears to offer great promise as a serologic diagnostic test in rheumatoid arthritis They reported a significantly high degree of accuracy, with few false-positive results After using their test for a short time, we were able to confirm in general the work of Plotz and Singer and came to realize the very great potential of their test as a routine laboratory and so necessary to the clinical diagnosis of rheumatoid arthritis Rheins modified the technique to such an extent that only a drop of serum was needed and duration and degree of incubation were reduced, the test could be read grossly and thus became an easily applied method for general diagnostic survey in rheumatic diseases This was reported by this laboratory in discussion at the American Rheumatism Association Interim Session in Bethesda, Md, Nov 30, 1956[5] We have now extended our studies to a sampling of patients of sufficient number to be statistically significant, and we consider the test to be of such great importance and value to practitioners everywhere that we are reporting these studies in detail here

Method

To date, 2,000 serum samples have been tested from 1,208 patients in the rheumatic disease laboratory of the Ohio State University Health Center Three hundred ninety-four serum samples from 301 patients are excluded from the tables to follow because the necessary information was unobtainable or inadequate to establish diagnosis The remaining 1,606 samples have been collected from 907 patients whose clinical diagnosis, of rheumatic disease or otherwise, is established All patients with rheumatic diseases have been followed by one or more of us in the arthritis division

In all cases, a definite commitment as to clinical diagnosis was made by at least one of us prior to the performance of the latex fixation test, so that no bias in clinical diagnosis was produced by positive or negative serologic results Also, the tests were performed by technicians unfamiliar with the patients' clinical diagnoses In addition, serum results and titers were recorded by a number rather than by name by the testing technician

Whenever possible, a Wintrobe sedimentation rate was performed on the same sample of whole blood from which the serum was tested by the drop latex fixation method Many of the 1,606 serum specimens are repeat samplings on patients after intervals of treatment

Classification

The 907 patients have been divided by clinical diagnoses into rheumatic and nonrheumatic groups (table 1) In the rheumatic group are included all patients whose major or minor complaint lay in a primary musculoskeletal disorder The following clinical standards were defined prior to evaluation of the test

Rheumatoid Arthritis—American Rheumatism Association criteria[1] are followed insofar as possible Included are active and inactive cases, treated and untreated, of any stage or grade, whether unaffected, partially suppressed, or completely suppressed by treatment Rheumatoid spondylitis is excluded

Rheumatoid Spondylitis—This condition was diagnosed by clinical and minimal x-ray criteria Active and inactive ("burned out") cases are included Also included for purposes of this paper are three patients with rheumatoid spondylitis in whom peripheral arthritis later developed

Osteoarthritis—This disease was symptomatic, with or without x-ray changes Included in this group are a few patients with well-defined post-traumatic arthritis Excluded, for purposes of this paper, are those patients with associated primary periarticular fibrositis

Fibrositis—Periarticular fibrositis, localized or generalized, is a symptomatic soft tissue disease of unknown or traumatic origin Included are patients with syndromes of known reflex origin such as shoulder-hand syndrome from coronary artery disease and carcinoma of the lung

Lupus Erythematosus—In this group are included only those patients with established clinical disseminated lupus erythematosus, either in remission or in relapse All but one have had positive L E cell preparations by the Hargraves technique on one or more occasions There are no patients with rheumatoid arthritis in this group

Diffuse Collagen Disease—The five patients in this group cannot be given a more correct diagnosis by clinical means All have been seriously ill with generalized connective tissue disorder, of which the arthropathy has been the least clinical concern

Infectious Arthritis—These patients had acute purulent arthritis without pulmonary disease or penetrating wound to the joint

Postgonococcic Arthritis—These patients developed sterile, purulent arthritis following culturally-proved gonococcic urethritis and vaginitis In all instances the arthritis responded to definitive antimicrobial therapy, and rheumatoid arthritis has not, thus far, appeared in any patient

Miscellaneous Diseases—Gouty arthritis, rheumatic fever (active), scleroderma, periarteritis nodosa, and Charcot joint require no further explanation of criteria for diagnosis All were established on proper clinical and laboratory grounds

In the nonrheumatic group are those patients with established clinical diagnoses other than in the rheumatic disease group Among these, however, are patients with diseases often accompanied by arthralgias (ulcerative colitis, osteoporosis, fracture into joint), diseases associated with abnormalities of serum proteins (hepatic cirrhosis, multiple myeloma), diseases comonly included among the collagen disorders (chronic glomerulonephritis, rheumatic heart disease [inactive]), and specific chronic infections (syphilis, pulmonary tuberculosis) known to produce bizarre results in some nonspecific serologic tests In 14 patients the diagnoses were unestablished, but were of nonrheumatic disease Seven patients were considered to have no disease

Technique

The technique of the drop latex fixation test is reported elsewhere[5] but is reviewed here in brief for purposes of clarity To prepare the antigen, mix 0 1 ml of stock suspension of latex particles (mean diameter 1 17 μ) with 9 5 ml of borate buffer (pH 8 2) in a test tube Add 0 5 ml of gamma globulin (poliomyelitis immune globulin containing 150 mg of gamma globulin was diluted so that each milliliter contained the recommended 5 mg per milliliter) Mix by inverting several times and store in refrigerator until needed (Usually, the antigen is used but one day, however, we have found it to be unchanged on the second and even the third day Regardless of the length of storage, it should be mixed by inverting just prior to use)

The initial dilution of all test serums is 1 20 As a routine procedure this is accomplished by mixing 1 drop of serum (no previous treatment necessary) into 1 ml of the borate buffer Frozen serum may be used Serum should be frozen if it is not to be used immediately

Two drops of each serum (1 20) to be tested are added to small culture tubes (12 by 75 mm) with disposable capillary pipets (these were found to be of fairly uniform bore—they should be long enough, 5 in , to reach the bottom of the tubes) Two drops of antigen are now added to each tube After mixing by shaking the test tube rack, incubate the tests in a 37 or 56 C water bath for 30 minutes The tubes are centrifuged (angle centrifuge) at approximately one-third speed (1,000 rpm for one minute) As soon as the centrifuge speed reaches the one-third setting, the centrifugation is discontinued and the tubes are removed and read by slanting them and observing under reflected light A positive test is indicated by discernible aggregation, a negative test by absence of aggregation Two controls are included (1) 2 drops of a known negative serum (1 20) plus 2 drops of antigen, and (2) 2 drops of buffer plus 2 drops of antigen The serum control was found to be extremely valuable, since the 1 20 dilutions of test serum have a viscosity greater than that of the buffer and lead to dubious results

All serums founds to be positive or doubtful are titrated For each titration, 9 tubes (12 by 75 mm) are placed in a rack Two drops of the buffer are added to each of the tubes but the first Two drops of the 1 20 test serum are added to the first tube (this permits an additional check on the screening procedure) and 2 drops to the second tube in the series The contents of the second tube are mixed by agitating the tube (shaking), and 2 drops of the 1 40 dilution are transferred to the third tube The mixing and transferring are repeated throughout the series Two drops from the last tube are discarded The serum dilutions range from 1 20 through 1 5,120 Two drops of the antigen are added to each tube, and the incubation (tubes are shaken first) is done as before Controls are included After centrifugation, the last serum dilution giving demonstrable aggregation (compare with controls) is the titration end-point For purposes of screening, all patients with a positive result in the first tube (dilution 1 20) are considered to have a positive latex fixation test

TABLE 1 —*Results of Latex Fixation Test in 907 Patients*

Diagnosis	No Positive	No Negative	Total No	% Positive
Rheumatoid arthritis	245	46	291	84 2
Rheumatic disease without rheumatoid arthritis	15	399	414	3 6
Nonrheumatic diseases	11	191	202	5 4

* Symptoms of rheumatoid arthritis without objective evidence

† Wrist joint swelling without other objective evidence of disease

‡ No objective signs of rheumatoid arthritis

Results in Rheumatic Disease Group

Rheumatoid Arthritis—Of 705 patients considered to have rheumatic disease (table 1), 291 met the clinical criteria for diagnosis of rheumatoid arthritis Of the 291, 245, or 84 2%, showed positive latex fixation tests This compares favorably with the results of others using various sheep cell agglutination techniques for the serologic identification of rheumatoid arthritis[6]

The false-negative reactions among the rheumatoid arthritis group are tallied individually in table 2 Included are patients with stage and class of disease from 1 to 4 In many cases, however, the disease is of low grade of activity, inactive, or completely suppressed by steroids or gold therapy In some instances, this is based on clinical evidence alone In others, however, concomitantly determined sedimentation rates are relatively low or normal (One should not conclude, however, that adequate suppression by steroid or gold therapy will necessarily inhibit the latex fixation test in a patient with active rheumatoid arthritis Many of the patients with positive latex fixation tests have adequate suppression of objective activity by therapy In general, however, the greater the activity, duration, and extent of disease, the higher the titer of the latex fixation test)

Table 3 —*Results of Latex Fixation Tests in 414 Patients with Rheumatic Diseases Other than Rheumatoid Arthritis*

Diagnosis	No Positive	No Negative	Total No
Osteoarthritis	4	147	151
Fibrositis	5	156	161
Rheumatoid spondylitis	0	30	30
Disseminated lupus erythematosus	2	15	17
Gouty arthritis	0	16	16
Rheumatic fever (adults)	1	12	13
Diffuse collagen disease	1	4	5
Scleroderma	1	2	3
Postgonococcic arthritis	0	3	3
Infectious arthritis	0	2	2
Charcot s neuroarthropathy	0	2	2
Psoriatic arthropathy	0	4	4
Reiter s disease	0	1	1
Serum sickness (TAT)	0	3	3
Periarteritis nodosa (fatal)	1	1	2
Tuberculous spondylitis	0	1	1
Totals	15	399	414

Also having the negative reactions were patients with atypical or mild disease (cases 1, 3, 6, 13, in table 2) and patients with early or prodromal rheumatoid arthritis (cases 2, 4) Thus, in some of these, the diagnosis of rheumatoid arthritis could be questioned

Rheumatoid Spondylitis —Patients with proved rheumatoid spondylitis were included in this group irrespective of past or present associated peripheral joint disease Although 3 of the 30 have now some involvement of distal joints by what is clinically active rheumatoid arthritis, no patient in this entire group has had a positive latex fixation test Most have had repeated tests, with negative results This lends some support to the thesis that the two diseases are at least serologically different Similar results have been reported by others with the sheep cell agglutination technique[7]

Osteoarthritis —Of 151 patients with clinical diagnosis of osteoarthritis, 4 had positive latex fixation tests It is not known whether the false reactors represent failure of the test or incorrect diagnoses (table 4)

Fibrositis —There were 5 false-positive reactors in 45 patients with fibrositis The same questions in clinical and serologic evaluation exist in these patients as in the osteoarthritis class (table 4)

Disseminated Lupus Erythematosus —There is apparently a distinct serologic separation of patients with rheumatoid arthritis from those with disseminated lupus erythematosus In this respect the drop latex fixation test appears to offer a distinct advantage over the known sheep cell agglutination techniques, in which false-positive results frequently occur However, the two false-positive reactions in this group occurred in patients who clearly did not have rheumatoid arthritis

Scleroderma —Of the three patients with scleroderma, two, with inactive nonprogressive distral scleroderma, had a negative latex fixation test The last, a young woman with clinically active but slowly progressive scleroderma, who has never had any arthropathy, had a strongly positive latex fixation test (dilution 1 5,120) (table 4) This, of course, requires further investigation, no other comment being possible

Others —Patients with gouty or postgonococcic arthritis, infectious arthritis, syphilitic neuroarthropathy, psoriatic arthropathy, Reiter's disease, tuberculous spondylitis, serum sickness, and diffuse collagen disease all had negative latex fixation tests consistently The numbers of all but the group with gouty arthritis are too small to warrant inference It is significant, however, that the most desperately ill patients with unclassified diffuse collagen disease involving all fibrous structures, including synovial tissues, showed negative latex fixation tests None are dead, none are well, and none have settled down into clinically recognizable rheumatoid arthritis

Results in Nonrheumatic Disease Group

Many patients in the nonrheumatic group were selected because of clinical association with the rheumatic diseases, as in rheumatic heart disease, chronic ulcerative colitis chronic glomerulonephritis, osteoporosis, and healing stage of fracture into a joint Others were chosen because of known associated serologic abnormalities, i e, multiple myeloma, cirrhosis of the liver, histoplasmosis, and syphilis The remainder are patients chosen at random from inpatient services One hundred ninety-one of the 202 patients in this group had negative drop latex fixation tests Two with positive reactions had a positive serologic test for syphilis (STS) (table 5) Both had histories of adequate treatment for presumed latent syphilis (Five patients found to have a positive STS with unassociated disorders had negative latex fixation tests This will be discussed later)

Table 4 —*Titer of False-Positive Latex Fixation Test in Patients with Rheumatic Diseases Other than Rheumatoid Arthritis*

* Weak reaction
† Repeat test negative

The remaining false-positive reactors in this group include a patient with cerebrovascular accident, one with generalized symptomatic osteoporosis, and the mother of one of the young patients with lupus erythematosus (This woman has had arthralgias and may have had rheumatoid arthritis in the past) The overall significance of the findings in the nonrheumatic group lies in the low incidence of false-positive reactors among the hospital population, even though chosen because of clinical or serologic similarity to patients with rheumatoid arthritis

Comment

For a test to meet the needs of physicians as an aid to clinical diagnosis or estimation of disease state, it must be simple, short, easy to teach and perform, accurate sensitive, specific, reproducible, and inexpensive to initiate and carry out In addition, if such a test is considered for mass screening or survey work, the test must be stable for frozen serums, it must be adaptable to running large numbers of serums in unit time, and it must be reproducible not only by different technicians in the same laboratory but by other technicians in other laboratories The drop latex fixation test meets all these requirements except possibly sensitivity However the 16% failure of detection occurred in some early, inactive, and thoroughly suppressed cases of rheumatoid arthritis and only in an occasional instance of full-blown generalized, active, unsuppressed disease The reasons for these failures are unknown, but are experienced to a like degree by those using standard sheep cell techniques

The number of patients having false positive tests is low (26 in 616) Fifteen of these come from the nonrheumatoid rheumatic disease group (totalling 414) and 11 from the nonrheumatic group (totalling 202), suggesting that the incidence of false-positive reactions may not be greater in those with nonrheumatoid rheumatic disease than in a general hospital population

TABLE 6—*Data on Patients with Nonrheumatic Disease Who Had False Positive Latex Fixation Tests*

* Three repeat tests were negative

Since the number of adults with active rheumatic fever was small, serums were obtained from 22 children hospitalized because of active rheumatic fever These patients were not examined by either of us, but the serums were obtained for a separate study for validation of the serologic differentiation of rheumatoid arthritis and rheumatic fever The absence of a single positive latex fixation test in this group is noteworthy

Earlier, allusion was made to positive latex fixation tests occurring in persons with known syphilis with one or more STS being positive Initial studies have failed to reveal significant correlation between serum reactivity to the antigens used for the STS and the latex antigen

In addition, 5 of 100 serums from patients with active pulmonary tuberculosis were positive by latex fixation technique Neither of these disorders should present any problem to the clinician in distinguishing them from rheumatoid arthritis, unless the rheumatic disease and infectious process coexist These findings are most interesting when considered in the light of the basic mechanism of the latex fixation test, about which literally nothing is known An interesting sidelight which should be investigated further is the occurrence of a positive latex fixation test in some cases of serologically proved syphilis There are two instances of overlap of lupus, positive STS, and positive latex fixation test in this series

Summary and Conclusions

The drop modification of the latex fixation test has been performed as a screening procedure on 2,000 serums from 1,208 patients Of 291 patients with rheumatoid arthritis, 245 had positive serologic tests, for an over-all efficiency of 84 2% There were 3 6% false-positive results among the 414 patients with nonrheumatoid rheumatic disease None of these occurred in patients with rheumatoid spondylitis, gouty arthritis, or infectious arthritis due to any cause False-positive reactions occurred rarely in disseminated lupus erythematosus, acute rheumatic fever, and in unclassified diffuse collagen disease These results compare favorably with those reported for the various sheep cell agglutination tests for serologic detection of rheumatoid arthritis

Because of ease, simplicity, speed, specificity, relative sensitivity, inexpensiveness, and adaptability to large volume work, the drop latex fixation test has been used in this study to determine its value as a single laboratory diagnostic procedure in rheumatoid arthritis It appears that the drop latex fixation test offers the only convenient specific laboratory aid to clinical evaluation of presence or absence of rheumatoid arthritis Further studies as to the mechanism and adaptability of the test are in progress Work is presently being done to adjust the test to encompass the more deliberate examination of the so-called false-negative serums If the test is found to be as consistently reliable as it appears thus far to be, its use in large clinical studies and perhaps mass-screening procedures will be indicated

Chlorpromazine Toxicity —Chlorpromazine-induced jaundice is of the intrahepatic cholestatic type, and there is usually no associated hepatocellular damage Nevertheless, several deaths from chlorpromazine hepatitis have been reported Since the clinicopathologic syndrome of primary intrahepatic cholestasis may have diverse causes, the jaundice may offer considerable difficulty in differential diagnosis Jaundice may occur several weeks after discontinuing the drug, and it may persist for many months, irrespective of the amount of drug given In cases of obstructive jaundice in which careful questioning of the patient discloses recent intake of even small amounts of chlorpromazine, operation should be deferred until a complete investigation is made to rule out the possibility of drug toxicity The transaminase test is valuable in excluding the possibility of concurrent exposure of patients to other hepatotoxic or icterogenic agents or conditions Increased transaminase activity has been found to precede the development of jaundice from chlorpromazine During the first two months of therapy a urinalysis [should] be done for bile twice a week, and frequent white cell counts [should] be made during this period especially when fever, sore throat, or skin eruption suggests the presence of sensitivity to the drug If the blood serum appears icteric, serum bilirubin, alkaline phosphatase activity, and other liver functions studies are indicated, as all cases of toxic reactions should be carefully studied However no laboratory data can be substituted for careful, continued, clinical observation of the patient It would seem wise to avoid chlorpromazine therapy when infectious hepatitis is endemic, in the presence of liver disease, in malnourished patients, and when other potentially hepatotoxic agents have been used —Lieut Col W L Craddock, M C , U S Army (Res), Toxic Effects of Chlorpromazine, *United States Armed Forces Medical Journal,* December, 1956

ETIOLOGY OF THE TRANSIENT CEREBRAL STROKE

Sanford F Rothenberg, M D
and
Eliot Corday, M D, Los Angeles

• Hemiplegia, monoplegia, hemianesthesia, aphasia, and visual disturbances are all manifestations of sudden, transient focal cerebral vascular disturbances Rhesus monkeys, whose pial vessels are similar to those of man, were studied to clarify the etiology of these transient cerebral strokes The results of the experimental studies suggest it is unlikely that cerebral angiospasm can occur, but rather that the transient cerebral stroke is due to cerebral thrombosis, embolism, hemorrhage, or vascular insufficiency The concept of cerebral vascular insufficiency which explains many of the transient neurological disorders is caused by disturbances of the systemic circulation in the presence of cerebral artery narrowing

The etiology of sudden, transient focal cerebral vascular disturbances has been the subject of considerable controversy [1] Such disorders include hemiplegia, monoplegia, hemianesthesia, aphasia, and visual disturbances They occur suddenly and often disappear rapidly, sometimes within a few minutes Consciousness is frequently maintained In the absence of other obvious causes for these attacks, it has been convenient in the past to attribute them to cerebral angiospasm

Recent investigations,[1] however, have raised serious doubt concerning the ability of cerebral arteries to contract It is, of course, well known that many visceral and other arteries are capable of constriction in response to various stimuli These vessels are supplied with adequate musculature and innervation which function to narrow the arterial caliber The cerebral arteries, however, as shown by Pickering,[1b] are lacking in vasoconstrictor innervation and musculature It is difficult to see, therefore, how contraction of these vessels can occur Hence, Pickering suggested that small focal cerebral vascular disturbances might be embolic or thrombotic in origin Others have suggested that "small strokes' may be the result of minute cerebral hemorrhages The duration of dysfunction in such episodes would presumably be related to the adequacy of the local collateral circulation

Despite the evidence presented by Pickering, many clinicians still regard cerebral angiospasm as the mechanism responsible for small strokes The presumed presence of cerebral angiospasm is the basis for anesthetizing the stellate ganglion in some instances of cerebral vascular disorders This procedure is supposed to abolish or prevent cerebral vasospasm by blocking vasoconstrictor impulses to the affected vessels However, it has been postulated that anesthetization of the stellate ganglion improves the cerebral circulation by its effect on the systemic circulation or the extracranial arteries rather than by abolishing spasm of the intracranial vessels

Because of the difference of opinion concerning the actuality of cerebral angiospasm, it was decided to investigate this question experimentally The animals chosen for this study were rhesus monkeys, whose pial vessels are similar anatomically to those of man Our results differ from those of Forbes and co workers,[2] who mainly observed dogs and cats However, the interpretation and statistical significance of their results have been questioned [1a] We used monkeys because of the closer correlation of the cerebral vasculature of this species to Homo sapiens As a result of this study, it was concluded that these vessels do not constrict on direct external stimulation of various kinds, nor does active contraction occur after systemic administration of various agents

Methods and Results

Fifteen rhesus monkeys were anesthetized with pentobarbital in doses of 0 5 grain (0 032 Gm) of the drug per kilogram of body weight An opening was made in the skull, and the meninges were reflected or removed over the area to be studied In two experiments, a Lucite window was screwed tightly in place over the exposed pial surface With a special camera, photographs of the blood vessels were made, these were later projected on a screen and magnified about 500 times This magnification permitted accurate measurements of the width of the vessels and of any significant changes in their caliber

Photographs were made before and after each of the following procedures, with the camera kept in the same position throughout the experiment (1) stroking the pial surface with an applicator (fig 1) (2) application of hot and cold stimuli to the pial vessels (fig 2) (3) local application of epinephrine, (4) administration of epinephrine and arterenol intravenously (fig 3), (5) bleeding from the femoral artery, (6) blood transfusion, and (7) administration of hexamethonium (Bistrium) bromide (fig 4) The purpose of the first three procedures was to observe the effect of direct stimulation of various kinds upon the caliber of the pial vessels The last four procedures were designed to determine the effect of marked variations in systemic blood pressure

It was noted that, when ice or heat was applied to the pial blood vessels, no change occurred in the diameter of the vessels (fig 2) When the pial surface was stimulated by stroking (fig 1) or when epinephrine was applied topically, the size of the blood vessels did not change When the blood pressure was raised by the administration of epinephrine or ar-

---

From the Institute for Medical Research Cedars of Lebanon Hospital (Dr Rothenberg) and the School of Medicine University of California (Dr Corday)

Read at the 10th Clinical Meeting of the American Medical Association, Seattle Nov 29 1956 terenol, the diameter of the blood vessels increased considerably (fig 3) When hypotension was produced by bleeding the animal, the blood vessels decreased in size However, if the animal was then given a transfusion, the blood vessels returned to their normal size When the blood pressure was lowered by the administration of hexamethonium bromide (fig 4), the diameter of the blood vessels was again decreased

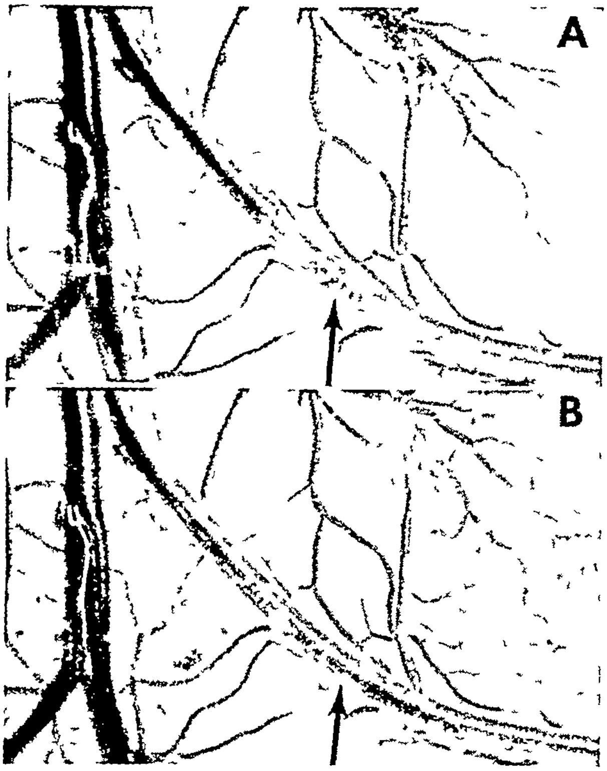

Fig 1 —Photomicrographs of pial vessels in rhesus monkey *A*, before stroking arterioles with applicator *B* after stroking arterioles with applicator Note that the vessels remain the same caliber even though the stimulation has produced capillary hemorrhages

Comment

The results of these experiments indicate that external stimulation of the pial vessels of the rhesus monkey does not produce changes in the diameter of these vessels No difference in their caliber could be demonstrated after stroking the vessels or after the application of hot or cold stimuli These findings strongly suggest that spasm of these vessels does not occur, at least not from external stimulation It is conceivable, however, that if it were possible to stimulate these vessels in the same manner from within, different results might be observed

Changes in the diameter of the pial arterioles were observed when significant changes in the systemic blood pressure were produced When the blood pressure was reduced by administration of hexamethonium bromide or by bleeding, there occurred a corresponding reduction in the size of the pial vessels When the blood pressure was raised by the administration of pressor agents or by transfusion, there was a corresponding increase in the caliber of the pial vessels These changes thus appear to be entirely passive and dependent upon the level of the pressure within the vessels

Of course, radiologists have claimed that they have demonstrated narrowing of the cerebral arteries with the injection of iodopyracet (Diodrast) compound into carotid arteries Walker,[2A] after viewing 800 cases of cerebral angiography, stated that he was not impressed that spasm of the intracranial arteries occurs and that he was unable to demonstrate spasm by using iodopyracet compound in the experimental animal In cerebral angiography the results are influenced by the techniques, the rapidity of injection of the contrast medium, systemic blood pressure, and the phase of cardiac cycle If the results are to be compared critically, all these factors must be uniform It has been demonstrated that the extracranial carotid arteries may constrict, therefore, it is theoretically possible that the radiologic changes which occur on one side of the brain might be only a reflection of the spasm of the large extracranial arteries rather than of the pial arterioles

The results of these experiments thus support the view that cerebral angiospasm does not occur, at least in the pial vessels When variations in the caliber of these vessels were observed, they invariably followed changes in systemic blood pressure This finding is in accord with the phenomenon of cerebral vascular insufficiency described by us and our co-workers[3] in 1953 Interest in this subject was aroused by the observation of sudden hemiplegia in a patient who had just suffered a severe gastric hemorrhage associated

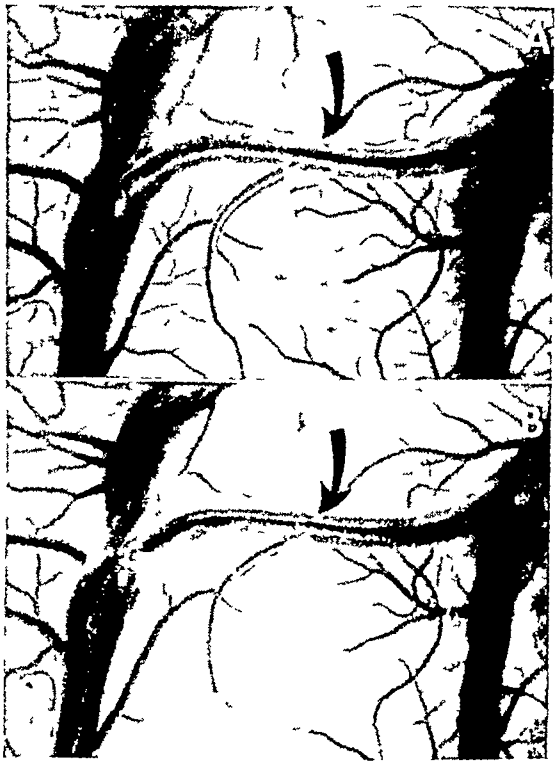

Fig 2 —Photomicrographs of pial vessels in rhesus monkey *A*, before application of ice to surface of brain *B*, after application of ice to surface of brain Note that the caliber of the arterioles does not change

with a marked fall in blood pressure As soon as the blood pressure was restored to normotensive levels, the hemiplegia disappeared

This observation led to a series of experiments in the monkey designed to elucidate the mechanism of this phenomenon [1a] It was shown that transient electroencephalographic abnormalities occur when systemic hypotension is produced in animals whose carotid arteries were narrowed on one side by a graduated occlusive clamp It was further demonstrated that the electroencephalographic changes could be reversed when the animal's blood pressure was restored to normal by transfusion or by the administration of vasodepressor drugs It was shown that the electroencephalographic changes were due to the drop in blood pressure itself and not to anemia Thus it appeared that a condition closely analogous to coronary insufficiency can occur with respect to the cerebral arterial system, and because the physiological phenomenon resembled that which occurs in the myocardium with narrowing of the coronary vessels, we termed the condition "cerebral vascular insufficiency

Many observers have reported cases in which transient or permanent focal and generalized signs or symptoms *occurred in the presence of occluded cerebral* arteries [4] However, this was the first time that it could be demonstrated experimentally that reversible ischemic signs could develop in the brain due to narrowing of the cerebral vessels without complete occlusion [3] In these studies, the development of cerebral ischemia (infarction) would seem to result from inadequacy of the collateral circulation in the presence of hypotension On the contrary, when the pressure was maintained at normotensive levels, the collateral blood flow was apparently capable of preventing the occurrence of significant ischemic changes in the region usually supplied by the narrowed artery

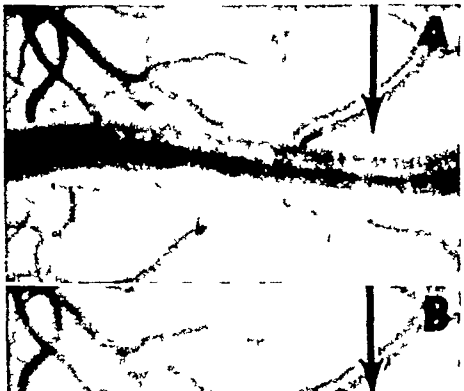

Fig 3 —Photomicrographs of pial surface in rhesus monkey, demonstrating that the arterioles of the brain increase in caliber as the systemic blood pressure is raised by parenteral administration of epinephrine A before administration of epinephrine, blood pressure 96 mm Hg B, after administration of epinephrine blood pressure 130 mm Hg

The results of the experimental studies strongly suggest that localized narrowing as the result of arteriosclerosis or congenital defect would predispose the patient to focal neurological changes in such form as hemiplegia and hemianesthesia when a hypotensive state occurs or when there is a disturbance of systemic hemodynamics The immediate factor responsible for these focal cerebral changes is a deficiency of systemic blood pressure required to sustain the capillary blood flow necessary to permit adequate cerebral cell metabolism When the blood pressure is normal, the capillary pressure distal to the narrowed or obstructed vessels is sufficient to supply the demands of cellular metabolism The cells of the nervous system are particularly vulnerable to nutritional deprivation, their blood supply cannot long be withheld without the occurrence of severe and irreversible damage It is well known that generalized cerebral effects can result from hypoxemia, hypoglycemia and anemia per se without a hypotensive state being present However it should be emphasized that the localized changes of cerebral vascular insufficiency occur mainly as a result of hypotension a diminished cardiac output, or a diversion of systemic blood flow to the extremities These focal changes include convulsive seizures, focal paralysis, aphasia, astereognosis, unilateral blindness, homonymous hemianopsia, hemianesthesia, and hemiplegia However, if the condition is of a more severe nature, general cerebral signs such as confusion syncope, and coma may result

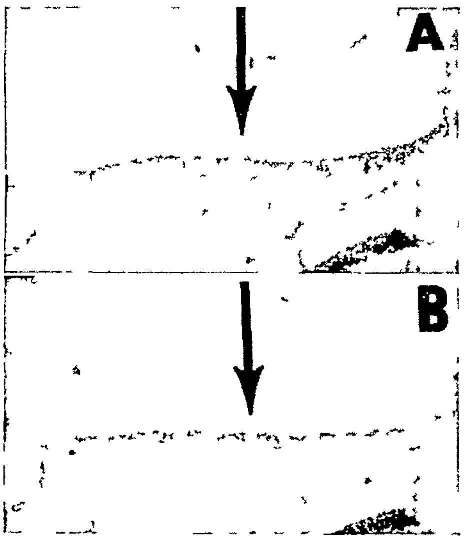

Fig 4 —Photomicrographs of pial arterioles in rhesus monkey demonstrating that arterioles decrease in size as systemic blood pressure is lowered by administration of hexamethonium (Bistrium) bromide A, before administration of hexamethonium blood pressure 132 mm Hg B, after administration of hexamethonium blood pressure 54 mm Hg

The concept of cerebral vascular insufficiency would appear in many instances to offer a more satisfactory explanation for transient cerebral disturbances than has previously been advanced This seems especially true in cases in which the same vessel is repeatedly involved It is not likely that thrombosis or embolism with recanalization would recur several times in a single artery Nor, in view of the experimental evidence presented earlier in this paper, does it seem probable that cerebral vascular spasm is responsible for these phenomena

Cerebral vascular insufficiency may be brought about by a number of different conditions The causes are as follows (1) hemorrhagic shock, (2) coronary shock, (3) anaphylactic shock, (4) insulin shock, (5) traumatic shock, (6) antihypertensive drugs, (7) postsympathetic disorders, (8) hypersensitive carotid sinus, (9) reflex vasodepressor phenomena, (10) postural hypotension, (11) gravitational states (aviation), (12) sleep (upright position), (13) surgical procedures, (14) anesthetics, (15) cardiac arrhythmias, (16) congestive heart failure, (17) pulmonary hypertension, (18) angiography, (19) thermal vasodilatation, (20) hypothermia, (21) Valsalva's maneuver, (22) pulmonary embolism, (23) labyrinthitis, and (24) sedative-hypnotic intoxication It will be noted that the factor common to all of them is systemic hypotension, or a disturbance in systemic hemodynamics

Among the more frequent conditions leading to cerebral vascular insufficiency are hemorrhagic shock, coronary shock,[5] cardiac arrhythmias,[3a] and carotid sinus hypersensitivity[6] It has been pointed out that patients may manifest cerebral phenomena as the only presenting symptoms in the presence of acute myocardial infarction or cardiac arrhythmias In such cases, the cardiac condition may be overlooked or thought unrelated to the symptoms of the nervous system unless one is aware of the possibility of cerebral vascular insufficiency resulting from cardiac disorders

It is of great practical importance to recognize cases of cerebral insufficiency, since only prompt correction of the hypotensive state can prevent irreversible cerebral damage

In view of the absence of vasoconstrictor innervation of musculature in the pial vessels, as demonstrated by Pickering,[1b] and the results of the experiments described in this paper, it appears unlikely that primary cerebral angiospasm can occur

Conclusions

Experiments performed on the rhesus monkey suggest that cerebral angiospasm does not occur Transient cerebral strokes are due to cerebral vascular insufficiency, thrombosis, embolism, or hemorrhage Cerebral vascular insufficiency is due to either cerebral vascular narrowing or an occlusion in the presence of systemic hypotension Prompt correction of the condition causing the hypotensive state in cerebral vascular insufficiency will prevent permanent cerebral damage

Atherosclerosis —The evidence is fairly conclusive that the circulating lipoproteins are the source of the increased lipids found in atherosclerotic vascular walls The physical state and particle size of the lipoproteins are important, probably due to the filtration properties of the vessel walls Studies of numbers of mast cells in animals and humans, and of circulating heparin levels, indicate that decreased heparin production in the body may be etiologically important in the accumulation of large amounts of circulating low-density serum lipoproteins An unfavorable chemical balance of androgen over estrogen often results in increased levels of beta lipoproteins, which appears to be the prerequisite to atherogenesis Treatment of 12 patients with 0 02 mg of ethinyl estradiol daily for seven weeks failed to produce consistent laboratory improvement Factors such as hypertension, diabetes mellitus, nephrosis, myxedema, local factors in the vascular wall, race, and eating habits unfavorably influence atherosclerosis — Col H C Gibson, Etiologic Aspects of Atherosclerosis *United States Armed Forces Medical Journal*, November, 1956

POSTERIOR PERFORATING PEPTIC ULCER

Herbert D Adams, M D
and
John R Ross, M D, Boston

• Analysis of 100 consecutive cases of posterior perforating peptic ulcer revealed that a patient with the presenting symptom of pain, particularly steady, continuous, and severe in the upper part of the abdomen or lower thoracic or back regions, often bizarre and not characteristic of ulcer pain, may well have a posterior penetrating peptic ulcer The first indication of the presence of a peptic ulcer may be the symptoms caused by perforation The location or even the presence or absence of pain due to a posterior perforating peptic ulcer is dependent upon the depth of perforation into the pancreas When the diagnosis has been established clinically and intractability is apparent, surgical intervention should be undertaken as early as possible to relieve the patient of his severe pain and also to avoid more serious complications associated with the pancreas

This study was undertaken in view of frequent difficulties in diagnosis and management of posterior perforation as a complication of peptic ulcer, both gastric and duodenal Symptoms of perforation may occur at any time during the history of peptic ulcer in an individual case In fact, the first indication of the presence of a peptic ulcer may be the appearance of symptoms caused by perforation Conditions governing whether or not perforation is to occur are not necessarily so conventional as commonly encountered in recurrent nonperforating peptic ulcer Those ulcers that eventually perforate seem to involve a combination of "virulence" and intractability as well as constitutional or tissue susceptibility to perforation The location or even the presence or absence of pain due to a posterior perforating peptic ulcer is dependent upon the depth of the perforation into the pancreas The encroachment on adjacent viscera and somatic nerve fibers necessarily broadens and varies the extent of the pain experienced by the patient In addition, marked variation also characterizes the appearance of the objective signs

Objective Signs

The extreme degree of edema, induration, and adhesions to adjacent structures, often associated with such perforations into the pancreas on roentgenologic examination often are indistinguishable from cancer of the stomach or pancreas When bizarre pain in the abdomen, chest, and back is present, although other conditions may be given prior consideration, pancreatic penetration of posterior wall peptic ulcer should be considered in the differential diagnosis The condition should also be suspected when pain from peptic ulcer becomes intractable under well-supervised and intensive treatment This impression can be confirmed by roentgenographic demonstration of a sharply circumscribed accumulation of barium upon the posterior wall of the stomach or duodenum Under these circumstances, a sign which is almost pathognomonic of pancreatic penetration is the demonstration of a broad zone of radiolucency ("halo" effect) about the pocketed barium upon the application of pressure at the site of the lesion The usual stellate pattern of the mucosal folds visualized radiographically converging upon an ulcer crater is, in posterior perforations lost at the zone of radiolucency about the crater (fig 1) The breadth of this nonopaque zone is proportionate to the depth of the perforation and the associated inflammatory reaction Frequently, air contrast mucosal studies, with the patient supine, add convincing evidence to this diagnosis

A patient with the presenting symptom of pain, particularly steady, continuous, and severe pain in the upper part of the abdomen or lower thoracic or back regions, often bizarre and not particularly characteristic of ulcer pain, may well have a posterior penetrating peptic ulcer At one extreme, some of these patients show little, if anything, on gastrointestinal x-ray study and thus have been branded psychoneurotics At the other extreme, some of these patients show great deformity of either the stomach or the pancreas strongly suggesting carcinoma of those organs, however, this may be difficult to differentiate even at the time of exploration

Review of Cases

One hundred consecutive cases of posterior perforating peptic ulcers were analyzed Of the 78 males and 22 females with the condition, 82 were between the ages of 30 and 60 years The presenting symptom of pain was severe in 72 patients and was located in the epigastric and back regions in 91 and 23 respectively Emesis was a symptom in 51 patients, and 9 had had a previous hemorrhage Obstructive symptoms were present in 19

The diagnoses were duodenal ulcer in 66 cases, with one at first thought to be carcinoma, gastric ulcer in 29, with 5 at first clinically designated carcinoma, and carcinoma simplex in one which at first had been thought a case of gastric ulcer There was no roentgenographic examination in the remaining four patients There were five deaths, two due to peritonitis and one each to intestinal obstruction, pneumonia and cerebral infarction after a fall that occurred postoperatively

Complications and Their Prevention in Surgical Treatment

When the diagnosis has been established clinically and intractability is apparent, surgical intervention should be undertaken as early as possible to relieve

---

From the Department of Surgery (Dr Adams) and the Department of Gastroenterology (Dr Ross), the Lahey Clinic the patient of his severe pain and also to avoid more serious complications associated with the pancreas The treatment of choice is subtotal gastrectomy, but the morbidity and mortality is higher in this group because of the higher incidence of serious complications primarily related to the duodenal stump or associated with the pancreas

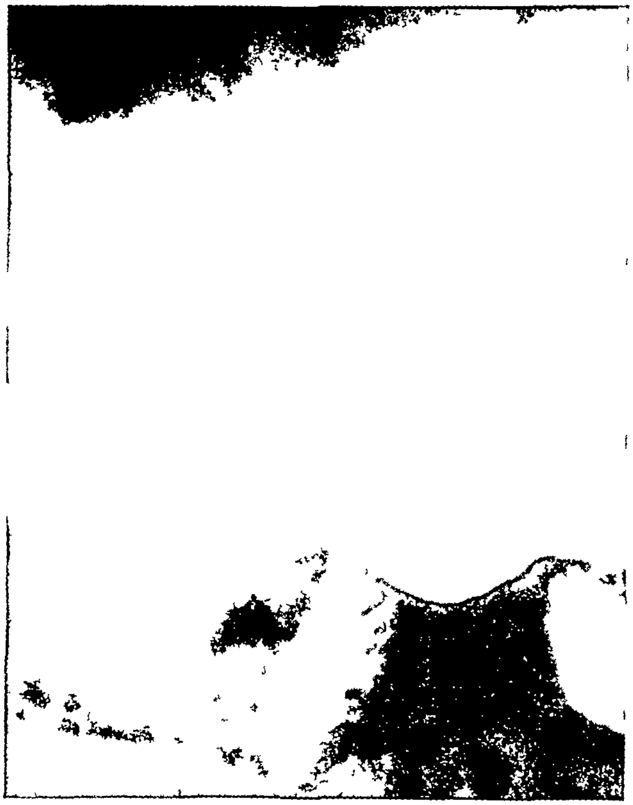

Fig 1 —Roentgenogram of posterior penetrating ulcer, demonstrating the broad zone of radiolucency (halo effect) about the pocketed barium upon application of pressure at the site of the lesion

Since in this group of complicated ulcers the chief hazards associated with resection are those relative to the pancreas and the duodenal stump, it is most apparent that one must carefully consider the basic causes for such complications and what measures can be taken to avoid them It is generally agreed by all surgeons that one should have the greatest respect for the pancreas as a potential source of serious complications when any type of surgery is being done in close anatomic relation to that important organ Any trauma, even minor, incision into, or even break in the capsule may result in either a severe pancreatic reaction or a pouring out of secretions into the surrounding tissues, with an associated potent enzymatic reaction and necrosis, delayed healing, and marked inflammatory reaction in the adjacent tissues Chemical necrosis and abscess and superimposed pyogenic infection on the resultant necrotic tissue lead to further complications Clinically, these complications are chiefly acute pancreatitis, subhepatic or subdiaphragmatic abscess on either side, biliary obstruction, pancreatic fistula, necrosis and breakdown of the duodenal stump with fistula, obstruction or leakage of the gastrojejunal anastomosis, or obstruction of either the efferent or afferent loop These complications may be single or multiple, and all will produce serious morbidity and mortality

Our experience has led us to believe that the majority of these complications can be prevented by certain technical precautions during resections of the adherent ulcers penetrating into the pancreas At the time this portion of the stomach or duodenum is mobilized from the pancreas, meticulous care should be taken to avoid damaging or opening up pancreatic tissue This can be accomplished only by careful dissection, under direct vision, of the surrounding adherent wall, with mosquito forceps and meticulous hemostasis being utilized When the actual bed of the ulcer is reached, no attempt should be made to dissect deep to it In the posterior perforated ulcer, the stomach or duodenal wall is no longer present and the base of the ulcer is represented by a granulating, sealed-off surface of the pancreas The margin of this ulcer should be carefully detached from the pancreas, with the granulated ulcer bed being left on the pancreatic surface undisturbed (fig 2)

The duodenal or stomach wall distal to the ulcer should then be carefully dissected from the pancreas until sufficient good pliable wall is developed to permit satisfactory closure of the stump This procedure should preferably be a three-layer closure a mucosal layer made by inverting continuous absorbable surgical sutures, a serosal-muscular layer made by continuous, inverting, Lembert, absorbable surgical sutures, and finally a serosal-muscular layer of interrupted Lembert sutures of silk Turning in large

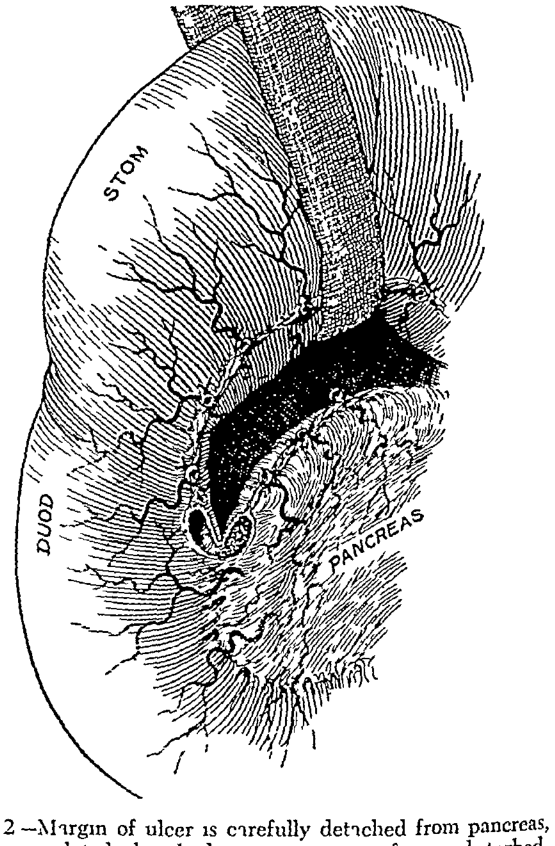

Fig 2 —Margin of ulcer is carefully detached from pancreas, leaving granulated ulcer bed on pancreatic surface undisturbed

amounts of wall with each of these layers should be avoided The completed suture line should not be buried in the pancreas, but the stump and the surrounding pancreatic surface should be covered with adjacent mesentery with interrupted sutures

The stomach is then mobilized on both mesenteric borders, with the left gastric artery and the short gastric arteries ligated so that approximately two-thirds to three-fourths of the stomach may be resected If a high resection is done, the anatomy in most patients is such that it is difficult to apply a von Petz clamp satisfactorily at this level If such a clamp cannot be used satisfactorily and in order to obtain the satisfactory hemostasis that is absolutely essential for excellent function of the gastrojejunal stoma, the following technical method has been developed The serosal and muscularis layers of the stomach are carefully incised transversely across the stomach, both front and back, at the approximate level of resection, with exposure of the large vessels as they lie in the submucosal layer These well-visualized vessels are then ligated in continuity individually with fine silk sutures (fig 3), this will control effectively the major portion of the bleeding from the transected stomach edges when this final layer is divided This avoids the difficulty of securing these vessels, which retract under the mucosa if all layers of the stomach are simply cut across

Since British investigators [1] have shown conclusively that there are arteriovenous communications in the vascular bed of the stomach wall, it is obvious why these blood vessels in the gastric wall have such high pressure and bleed so profusely and why the stomach will survive when such a great part of its major blood supply is shut off during various types of surgical procedures If any of these vessels with high pressure are not meticulously ligated in that portion of the stomach wall used for the anastomosis, there will be varying degrees of submucosal hemorrhage and hematoma surrounding the stoma, this will account for the delay in emptying the gastric stump, which delay may last for days to weeks after the operation This will necessitate prolonged tube drainage until the hematoma has been absorbed In some cases, it is possible even to demonstrate this process by visualizing with barium a smooth doughnut-like ring around the stoma In many cases, this postoperative delay in emptying of the gastric stump can be avoided by meticulous hemostasis, with the method described being used

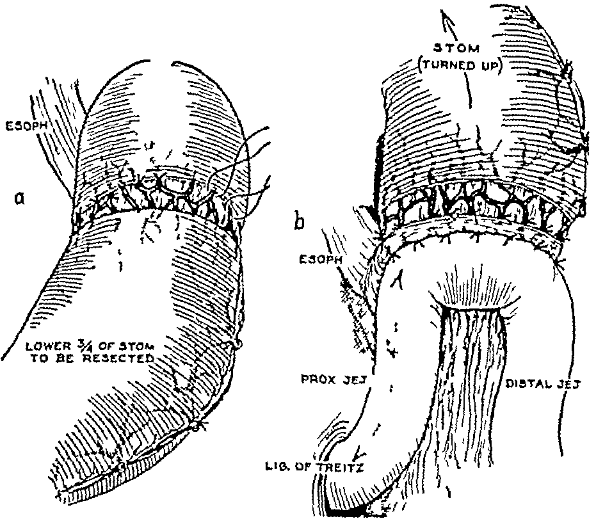

Fig 3—*A*, serosal muscularis layers incised, exposing large vessels in submucosal layer *B*, ligation of large vessels in continuity individually

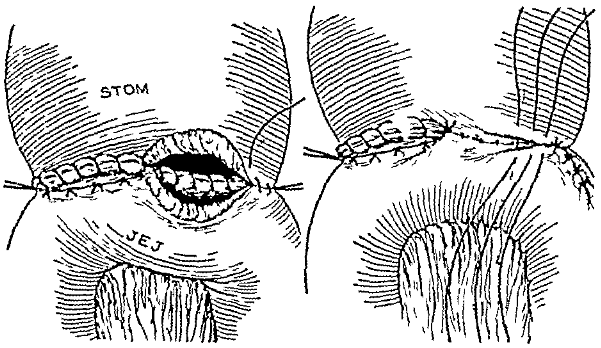

Fig 4—Completed anastomosis

Another important technical point to be discussed is the desirability or the undesirability of twisting the jejunal loop in making the union with the stomach, in other words, whether the loop is placed isoperistaltically or antiperistaltically In addition, these latter designations are confusing, and the following terminology specifies more clearly distal end of the jejunal loop to the lesser or greater curvature or, vice versa, proximal end of the jejunal loop to the lesser or greater curvature As far as function per se goes, placing the loop in either direction is entirely satisfactory We prefer not to twist the loop and to place the distal end of the jejunal loop to the greater curvature, because it accomplishes two things which placing the loop in the other direction does not (fig 3*b*)

First, it places the afferent functioning arm of the jejunal loop over in the left lateral gutter, far away from the dangerous area of the duodenal stump and uncovered pancreas, so that, if complications do occur in that area, this jejunal loop will not become involved, thus obstructing the stomach Everyone is aware that most patients will survive properly handled duodenal and pancreatic fistulas provided the stomach is not obstructed and proper nutrition can be maintained Patients in whom the afferent jejunal loop is obstructed will almost invariably be those in whom the loop is twisted with this afferent arm lying near or across the acute inflammatory reaction associated with duodenal stump or pancreatic complications A feeding jejunostomy must then be resorted to, and usually this is unsatisfactory because of the length of time essential for recovering from these serious complications Second, by not twisting the loop a shorter loop can be utilized, establishing the anastomosis closer to the ligament of Treitz, since in the antecolic anastomosis the loop slides more laterally over the splenic flexure and does not have to ride over the more bulky transverse colon Another point of importance is to suture the jejunal loop across the entire diameter of the stomach, buttressing it over the closed portion of the stomach as well, in the Hofmeister modification, so that the jejunal loop does not hang by the stoma and has a broad attachment to the stomach in both planes (fig 4)

Comment

We are fully aware that many of these technical details are of a controversial nature and that there are other excellent methods of obtaining equally good results These are factors of great importance, however, and should be stressed more than they have been in the past By means of the modifications in technique discussed and, especially, complete avoidance of even minor pancreatic injury and special technical measures to provide meticulous hemostasis at the site of the anastomosis, a high percentage of complications and poor function can be prevented

SURVEY OF GASTROSCOPIC AND ESOPHAGOSCOPIC ACCIDENTS

REPORT OF COMMITTEE ON ACCIDENTS OF THE AMERICAN GASTROSCOPIC SOCIETY

Lieut Col Eddy D Palmer (MC), U S Army
and
C Wilmer Wirts, M D, Philadelphia

• *Over 890 endoscopists were asked to report accidents peculiar to their practice A report was compiled dealing with such accidents as encountered during a total of 267,175 gastroscopies and 40,540 esophagoscopies The purpose of this survey was to determine the calculated risks of these procedures and to accumulate information on the circumstances which apparently contribute significant hazards to transoral instrumentation Perforation was the main problem, but anesthetic reaction was not an inconsiderable threat The over all accident rate in cases of gastroscopy was 0 079%, and in cases of esophagoscopy, 0 25% The findings are interpreted in an effort to find ways to circumvent accidental endoscopic injury*

As one of its avowed responsibilities, the American Gastroscopic Society initiated, in 1955, a world-wide survey of experiences with gastroscopic and esophagoscopic accidents The purposes were to determine the calculated risks of the procedures, as indicated by the combined experiences of many endoscopists, and to accumulate information on the circumstances which apparently contribute significant hazards to transoral instrumentation Interpretation of the findings reported here, in efforts to find ways to circumvent accidental endoscopic injury in the future, is believed to be the privilege and responsibility of those who take an interest in the results

The data which make up this report must be evaluated cautiously There are two main potential sources of misinterpretation A questionnaire survey asks the participant for specific information, but often the circumstances surrounding an endoscopic accident are such that specific answers cannot be furnished with unquestioned accuracy For instance, the answer to the question of whether an esophageal perforation was recognized immediately or only after a delay sometimes must be based on very vague retrospective feelings about the course of events immediately following instrumentation Similarly, if the patient survives a perforation without surgical exploration, it may be very difficult to specify with any assurance the actual site of the perforation, nevertheless, the answer must necessarily appear on the question sheet as a seemingly precise bit of information

Secondly, many of the data are of such a nature that it is easy to assume that they can be compared with each other In the absence of information on the conditions which exist during endoscopy which is not attended by accidents, however, certain comparisons must not be attempted Thus, most gastroscopic perforations were made with an instrument of a certain design, but this is merely a reflection of the fact that most gastroscopists regularly employ instruments of this design, not that there is necessarily any inherent danger in it The same is true for the anesthetic agents which caused most reactions Similarly, individual accidents of the same general nature assume various degrees of severity, and many factors have a bearing the outcome If the results of surgical intervention after perforation seem better or worse than those of medical management, it is just as likely to be the seriousness of the injury as the type of treatment which made the difference

Scope

A questionnaire on gastroscopic accidents and one on esophagoscopic accidents were sent to each of 890 doctors who were known or believed to be active in endoscopic work The mailing lists were taken from the membership rosters of the American Gastroscopic Society, the American College of Gastroenterology, the American Gastroenterological Association, and the American Broncho-Esophagological Association In addition, Dr F Avery Jones of London furnished a list of the 40 British gastroscopists who had contributed to his accident survey of 1951,[1] and 40 other personal acquaintances in foreign countries were contacted

Replies were received from about one-third of the doctors who were invited to participate It was found that 204 gastroscopy and 119 esophagoscopy questionnaires from a total of 260 participants were suitable for use in the compilations The main reason for rejection of reports was unavailability of figures to show the total number of procedures carried out In particular, many of the more experienced esophagoscopists found that it was not possible to compile figures to cover their total series This report deals with the accidents encountered during a total of 267,175 gastroscopies and 40,540 esophagoscopies The geographical origins of the reports which were utilized were as follows continental United States, 224, Hawaii, 1, Puerto Rico, 1, Canada, 2, Mexico, 2, Cuba, 1, Chile, 1, Argentina, 1, Venezuela, 1, England, 9, Australia, 2, Sweden, 1, Denmark, 1, Germany, 3, Switzerland, 3, Belgium, 1, Holland, 1, Spain, 1, Hungary, 1, Austria, 1, and India, 1

The report of each gastroscopist included his whole experience with the flexible gastroscope, therefore, although experience with the rigid gastroscope was not included, the reports of the older gastroscopists went back to the earliest days of modern gastroscopy, 1932, when means of treating accidental injury were not as effective as they now are It can be seen from the figures above that about half of the reporting esophagoscopists also reported upon gastroscopy Because the trend to expand the mission of the gastroscopy clinic to encompass medical esophagoscopy is a rather recent one, most of these participants reported on many more gastroscopies than esophagoscopies Thus, many of those who have been practicing diagnostic, as opposed to manipulative, esophagoscopy were relatively inexperienced at esophagoscopy, although not at peroral endoscopy Most of the other esophagoscopists, it is important to note, reported on experiences which included a large proportion of manipulative cases, particularly foreign-body problems and transesophagoscopic dilatations Although transoral manipulative techniques other than endoscopy were not included in the survey, there were, nevertheless, transesophagoscopic manipulations in many of the cases here reported

TABLE 1 —*General Experiences of Endoscopists*

	Gastro scopists	No of Gastro scopies Performed	Esophago scopists	No of Esophago scopies Performed
Totals	204	267 175	119	40 540
No accidents	109	72 511	75	11 631
Perforations	81	172 014	42	20 659
No accidents except from anesthetic	10	13 555	2	2,250
No accidents except postexamination bleeding and/or myocardial infarction	4	9 032		
Total no who had experienced anesthetic accident	20		5	
Total no who had experienced postexamination bleeding and/or myocardial infarction	9			

General Experiences of Participants

In table 1 are set forth the general experiences of the participating endoscopists Although the majority of gastroscopists and esophagoscopists had never encountered an accident, it is seen that these were the endoscopists who had had the smallest average experience It could not be concluded that the participants had exhibited more care in instrumentation when novices than after attaining the stage of extensive experience[2] Rather, it appeared that the simple law of remote chance eventually exerted its influence after an endoscopist had carried out enough examinations Other factors which were evident in the reports were that some of the experts had exposed their patients to unusual risks by experimenting with new instruments and new techniques and that others frequently accepted for examination poor-risk patients whom, as novices, they would have rejected

Accident Incidence

The over-all accident rate in cases of gastroscopy was 0 079% and in cases of esophagoscopy, 0 25% The over-all fatality rate for patients undergoing gastroscopy was 0 014% and for those undergoing esophagoscopy, 0 059% The types and incidences of the reported accidents are summarized in table 2 Perforation was, of course, the main problem, but anesthetic reaction was not an inconsiderable threat The other accidents (postexamination bleeding and/or myocardial infarction), which were encountered only in gastroscopic experience, were those which could not be ascribed with assurance to the procedure but which, nevertheless, must be considered gastroscopic accidents because of their chronology Six patients had bleeding from the upper gastrointestinal tract within 24 hours after gastroscopy In each patient the bleeding stopped spontaneously The exact source was determined in none, and in none was the bleeding of serious import Five other patients suffered acute myocardial infarction and died The onset of symptoms occurred in one patient on the way to the gastroscopy room, during preparation of one patient, during examination of two patients, and one-half hour after gastroscopy was performed in one patient In two cases instrumentation was not carried out

Perforations During Gastroscopy

The 163 perforations experienced during gastroscopy resulted in 25 deaths Eighty-three perforations occurred in women and 76 in men (4 not stated), and 17 deaths occurred among women as compared with 8 among men The number of deaths per age decade from the third through the seventh decades were, respectively, 2, 1, 7, 10, and 5

TABLE 2 —*Summary of Accidents*

	Gastroscopy			Esophagoscopy		
	Accidents	Deaths	Autopsies	Accidents	Deaths	Autopsies
Perforations	163	25	22	95	22	10
Anesthetic	36	8	6	6	2	2
Postexamination bleeding and/or myocardial infarction	11	5	3			

The general design (not manufacturer) of instrument and type of gastroscopic tip which had been employed in the instances of perforation are shown in table 3 Because it is not known relatively how frequently the various types of instrument are used by gastroscopists, the incidence figures give no information regarding the relative safety of the various designs The instrumentation was considered by the endoscopist to have been easy in 117 cases of perforation and difficult in 38 (not stated in 8) The figures for the fatal cases were 20, 4, and 1 The accident was recognized within 30 minutes of passage of the instrument in 81 instances and only after a delay (more than one-half hour to two days) in 78 instances (not stated in 4) Among patients who eventually died as a result, recognition of perforation was immediate in 16 and delayed in 9 instances

The stomach was the most common site of perforation (table 4), and, surprisingly, a perforation in this site proved to be a moderately dangerous accident Perforation of the distal portion of the esophagus was, as expected, the most dangerous type Centimeter for centimeter, the region of the hypopharynx and adjacent proximal esophagus proved most vulnerable to perforation, although the results of treatment were especially good In two instances the jejunum was perforated during examination of the stomach postoperatively, and in another the gastroscope was passed by error into the trachea, with perforation of the right bronchus

TABLE 3 —*Type of Equipment Used in Performing Gastroscopy in Instances When Perforations Occurred*

	No	Deaths

Castroflex	1	0
Not stated	10	1
Type of tip		
Rubber finger	138	22
Bullet	6	1
Sponge	1	1
Ball	1	0
Not stated	17	1

Eighty-four of the 163 cases of perforation were managed by surgical drainage, 68 by medical treatment alone, and in 11 instances the form of therapy was not stated The site of perforation had very little bearing on the decision regarding operative intervention In about half the patients with each type of perforation surgical drainage was used There were 16 deaths among the surgically managed patients and 8 among those treated medically only (one not stated)

The apparent explanations for each of the perforations, as judged by the examiner from clinical, surgical, and/or autopsy study, are outlined in table 5 The direct causes of death among the 25 perforation fatalities are shown in table 6 Although mediastinitis was the most frequent cause, *peritonitis and the late* sequels of peritonitis were common Some, but not all, of the deaths due to infection occurred during the early days of gastroscopy, prior to development of efficient antibacterial drugs

TABLE 4 —*Sites of Perforations Occurring During Gastroscopy*

	No	Deaths
Pharynx	19	1
Upper ⅓ esophagus	36	3
Middle ⅓ esophagus	3	0
Lower ⅓ esophagus	26	9
Stomach	75	12
Jejunum	2	0
Bronchus	1	0
Not stated	1	0

Perforations During Esophagoscopy

Ninety-five perforations resulting in 22 deaths were reported during esophagoscopy Fifty men and 45 women were injured, and the fatalities occurred in 13 men and 9 women The number of deaths per age decade from the first through the ninth were, respectively, 2, 0, 3, 0, 2, 8, 4, 1, and 1 (not stated in one case) The examinations which resulted in perforation were considered by the examiner to have been easy in 35 cases and difficult in 49 Eight of the former group and 9 of the latter died The information was not given for the other examinations Perforation was recognized immediately in 41 instances and not until more than one-half hour had elapsed in 54 Among the fatal cases, recognition of perforation was immediate in 9 and delayed in 12 (not stated in one)

The majority of perforations occurred through the hypopharynx and upper part of the esophagus (table 7) Proportionately, the more distal perforations proved considerably more dangerous In many instances the esophageal disease which led to the esophagoscopy appeared to be the direct explanation for the perforation The incitant proved to be a foreign body in 16 cases, carcinoma in 15, corrosive (lye) esophagitis in 11, stricture in 9, diverticulum in 4, atresia in 2, achalasia in 1, and nonspecific esophagitis in 1 There was no evident incitant in 36 cases It is important to note in this connection that in the foreign-body *cases it was often not possible for the esophagoscopist* to distinguish perforation due to the foreign body itself from that due to subsequent transesophagoscopic manipulation and that, whichever the case, these were accidents due to operative, not diagnostic, esophagoscopy The situation was rather similar in the stricture cases because, in some, the examiner had used the esophagoscope for dilatation purposes

TABLE 5 —*Inciting Lesions for Perforations Occurring During Gastroscopy*

	No
Perforation through carcinoma or ulcer	12
Blowout of carcinoma or ulcer	2
Spinal osteophytes	2

Gastric adhesions	1
Passage of instrument into trachea	1
No inciting lesion or other explanation recognized	136

TABLE 6 —*Cause of Death in Patients with Perforation Occurring During Gastroscopy*

	No
Death during first few days	
Mediastinitis	10
Peritonitis	7
Tension pneumothorax	1
Simple pneumoperitoneum ? cause	1
Death during surgery for repair	
Death during anesthesia	1
Cardiac standstill	1
Death during convalescence	
Pulmonary embolus	1
Pneumonia	1
Subphrenic abscess	1
Chronic hepatic and pulmonary abscesses	1

A biopsy had been taken in 18 of the cases of perforation In one instance it was proved that the biopsy had caused the perforation Surprisingly enough, more esophagoscopic perforations were treated by medical means alone (54) than by surgical drainage (37) The method was not stated for 4 cases There were 15 deaths among patients treated medically and only 3 *among those operated on The method of treatment* was not stated for 4 of the fatal cases The causes of death of the 22 patients with esophagoscopic perforation were mediastinitis in 16 cases, empyema in 2, purulent pericarditis in 1, pulmonary embolus in 1, and pseudomembranous enterocolitis in 1 The cause was unexplained in 1 case

Accidents Related to Use of Anesthetics

Because of the similarity of techniques and agents employed experience with anesthetic accidents during gastroscopy and esophagoscopy have been combined (table 8) There were, then, a total of 307,715 cases reported on, and it is assumed that some form of anesthesia was used for every patient This assumption is not absolutely correct, but it is known from the reports and from personal inquiry among the participating group that all of the endoscopists almost always give the patient some pharmaceutical preparation—here loosely termed anesthetic—prior to instrumentation In almost all cases of reaction more than one drug was used for preparation, but, because the different ones are ordinarily used at different intervals prior to instrumentation and because reaction to those used for local anesthesia appears quickly after administration, the participants in all cases were willing to specify which drug was at fault when reaction occurred

Lower 1/3 esophagus	22	8

Thirty-eight of the 42 accidents were due to a local anesthetic agent, and 10 of the patients died The four reactions ascribed to other drugs used for preexamination preparation were of little consequence Information was not obtained on the technique used for inducing anesthesia (swab, spray, or gargle) or on whether epinephrine was routinely added to the anesthetic solution In 18 instances a barbiturate had been used for premedication, in 10 it had not, and for 10 the information was not stated The main clinical manifestations during the reactions were convulsions, cardiac arrest, cyanosis, sudden shock, and coma When death occurred, it did so within a few minutes Treatment in almost all cases consisted of intravenous administration of oxygen and a barbiturate, with or without artificial respiration In two instances the chest was immediately opened for manual cardiac massage, and there was one survival

• *Human and primate cells in culture were used to establish viral etiology for aseptic illnesses involving the central nervous system not proved to be polio myelitis This program of laboratory studies resulted in recognition and etiological specification of epidemic aseptic meningitis occurring in Minnesota in the summer and autumn of 1956 Tissue culture methods permitted characterization of the epidemic as an outbreak of Coxsackie virus infection restricted, as had not previously been observed, to a single immunotype This finding provides further evidence that viruses other than the three known types of poliovirus may cause clinical illness designated as nonparalytic poliomyelitis until the causative agent is recovered and identified*

Etiological distinction of human illnesses previously grouped by clinical diagnosis as nonparalytic poliomyelitis and/or aseptic meningitis recently became possible by use of tissue culture methods now widely applied to virus investigations[1] Each year since 1946, studies in this laboratory incidental to identification of more than 1,000 wild strains of poliovirus have yielded viruses of the Coxsackie B subgroup from patients hospitalized during the poliomyelitis season with symptoms clinically diagnosed as "nonparalytic poliomyelitis" Most of these diseases could be classified as aseptic meningitis In addition, from 20 to 40% of patients hospitalized with a clinical diagnosis of poliomyelitis[2] annually failed to yield poliovirus It seemed reasonable that directed study of these findings, seemingly connected only by the classification of 'nontypical polio," might lead to recognition of one

---

From the Department of Bacteriology and Immunology, University of Minnesota Medical School, and Division of Medical Laboratories Minnesota State Board of Health Dr McLean is now with the Commonwealth Serum Laboratories, Melbourne, Australia

or more specific infections Accordingly, in 1956 a program was initiated to establish viral etiology for each aseptic illness involving the central nervous system not proved to be poliomyelitis, by use of a variety of human cell strains in continuous culture together with primary monkey kidney cell cultures The occurrence of epidemic aseptic meningitis in Minnesota in the summer and autumn of 1956 and the hitherto unobserved restriction of the cause of an outbreak of Coxsackie virus infection to an agency of a single immunotype provided unique opportunity for etiological specification of a variety of the aseptic meningitis syndrome This paper reports the laboratory, clinical, and epidemiologic findings for patients from whom virus was recovered

Laboratory Methods

The program of laboratory studies was implemented on reception of materials following the 1956 poliomyelitis epidemic

Specimens —Specimens for laboratory examination were obtained immediately upon admission to hospital of each patient with a diagnosis of nonparalytic poliomyelitis as follows (*a*) fecal samples were collected in paper cartons on two consecutive days, (*b*) swabs of oropharyngeal and tonsillar areas of the throat were taken, and (*c*) samples of cerebrospinal fluid and blood were obtained aseptically Venous blood was drawn on admission and approximately 10 days later to provide acute and convalescent phase samples for antibody assay From 1 to 11 days had elapsed between onset of clinical illness and collection of specimens

Examinations for Virus —Examinations for virus were done on each specimen by use of HeLa stationary cultures as previously described [1a] Fecal extracts representative of 19 patients also were inoculated in triplicate into stationary tube cultures of (*a*) monkey kidney cells dispersed from tissue with trypsin [1b] and (*b*) human esophageal and liver cells of established and clonal strains respectively

Identification of Unknown Cytopathogenic Viruses —Identification of unknown cytopathogenic viruses was necessary in 62 instances, 47 of 109 cytopathogenic agents isolated from materials submitted during the 1956 season were identified as polioviruses Cerebrospinal fluid was obtained from 13 of the 62 patients whose fecal samples gave evidence of nonpoliomyelitic infection, throat swabs were provided by 28, and paired serum samples by 46 Each of the 62 unknown virus strains was examined by incubation of 30 to 300 tissue-culture doses (TCD_{50}) with pooled monkey antiserum for one hour at room temperature, followed by inoculation of 1-ml aliquots of serum-virus mixture into four tube cultures of HeLa cells, assays also were done with human esophageal or liver cells and monkey kidney cells as indicated The pooled monkey antiserum contained 20 antibody units to each of Coxsackie virus immunotypes B1, B3, B4, and B5 and 6 antibody units to B2 virus Cultures were inspected under the microscope daily for four days to detect cytopathogenic effect Antibody titers were calculated by Reed-Muench interpolation [3]

Antibody Assays —Antibody assays were performed on patients' serums diluted 1 10 in cell-culture maintenance medium, heated at 56 C for 30 minutes, then finally diluted 1 50 and 1 250 Test virus titers were determined on each day of test The two final dilutions of paired serums from 42 patients were tested with 100 TCD_{50}, respectively, of types 1-3 polioviruses and Coxsackie B5 virus Serum pairs from 32 of the patients were retested similarly with both 300 and 1,000 TCD_{50} of stock Coxsackie B5 (prototypical Faulkner strain) virus and/or virus isolated from the patient and with 100 TCD_{50} of Coxsackie B3 virus Serum dilutions were mixed with test virus in equal volume and incubated for one hour at room temperature One milliliter aliquots of each test mixture were transferred to four HeLa, human esophageal, human liver, or monkey kidney cell cultures washed free from medium Results were determined as in the virus identification test

Results

Virus Isolations —In the Minnesota outbreak of aseptic meningitis, Coxsackie virus strains were isolated from 62 patients who became ill between July and December, 1956 Two or more stool specimens were obtained from 45 of 61 patients excreting Coxsackie B5 virus 37 patients exhibited virus in each of 2 specimens, while each of five patients gave one negative specimen Of three stool specimens from one patient, only the later two contained virus, one patient gave four specimens all containing virus, while another submitted four samples of which only the first contained virus Coxsackie B5 virus was isolated from stools collected as early as one and as late as 13 days after onset of illness B5 virus was found in throat washings from 15 of 28 patients from whom specimens

* Hyperimmunized with prototype Coxsackie B5 Faulkner strain prototype virus with hyperimmunized hamster serum received from Dr Dalldorf of the New York State Department of Health yielded an antibody titer of 5 000

were obtained from 1 to 12 days after onset but was not isolated from cerebrospinal fluid Wild B5 strains isolated in HeLa cell cultures from 36 patients uniformly produced acute encephalitis and death 5 to 14 days after intracerebral injection into two or three litters of newborn mice Only one patient suffering aseptic meningitis during the 1956 season excreted virus other than Coxsackie B5 strain B3 Coxsackie virus was obtained from feces and throat washings

It was interesting to note uniform sensitivity of the HeLa, esophagus epithelial, liver epithelial, and monkey renal cells employed in comparative tests as indicators for field strains of Coxsackie B5 virus in stools of 19 patients In one instance the range of TCD$_{50}$ titers exhibited by the different cells for each virus strain exceeded the range of error typical of titrations done in this laboratory (0 3 log), but only by 0 1 log All of the cells thus were equally useful B5 virus infection in cells of the four types was reflected by cellular rounding, cytoplasmic granularity and shrinkage, nuclear pyknosis, and, finally, cell rupture and release of fragments from glass, similar to cytopathogenic effects of poliovirus infection in these cells

Neutralizing Antibody Assays —Tests for neutralization of prototypical Faulkner B5 virus by paired serums from 33 patients indicated fivefold or greater titer increases for 9 patients Four of these patients had no antibody in the first serum sample Antibody in the early serum sample from 12 patients was not followed by significantly increased titer of the second sample On test against 1,000 TCD$_{50}$ of B3 virus, paired serums from the patient yielding Coxsackie B3 virus exhibited titer increase from 10 to 50, antibody to B5 virus was absent from both early and late specimens Antibody to B5 virus was detected in serums obtained as early as the first day of illness from one patient or the second day from four patients Two patients lacked detectable serum antibody as late as 5 days from onset, although it was present 10 days later Ancillary tests showed for six patients (*a*) relative similarity of patient's serum titers for prototype B5 virus and patient's virus (table 1) and (*b*) failure of acute and convalescent-phase serums from patient 61 to distinguish prototype B5 virus from patients viruses by comparison with control monkey antiserum to prototype virus (table 2)

Epidemiologic and Clinical Findings —During 1956, Minnesota physicians reported 179 illnesses categorized as epidemic poliomyelitis to the state board of health Sixty-six patients had one or more limbs paralyzed 42 patients with paralytic and 5 with nonparalytic disease yielded viruses classified as 39 strains

of type 1 and 8 strains of type 3 poliovirus The 113 patients with no indication of paralysis, with various diagnoses, including nonparalytic poliomyelitis,' 'suspected meningitis,' virus meningoencephalitis,' "suspected lymphocytic choriomeningitis,' and 'aseptic meningitis,' yielded 62 viruses other than poliovirus Identification of 61 of these agents as Coxsackie virus, immunotype B5, indicated that epidemic aseptic meningitis had resulted from infection by a single Coxsackie virus Evidence against concurrent poliovirus infection was given by (*a*) failure to isolate poliovirus from any of the 61 patients with aseptic meningitis who yielded Coxsackie B5 virus, (*b*) insignificant changes in titer of antibody in 42 paired samples of patients' serum to types 1-3 poliovirus (table 3), and (*c*) occurrence of aseptic meningitis without relation to history of vaccination with formalin-inactivated trivalent poliovaccine Prior to outbreak of aseptic meningitis, 6 patients had received one injection of vaccine, 23 had received 2, and one had received 3, 31 had not been vaccinated

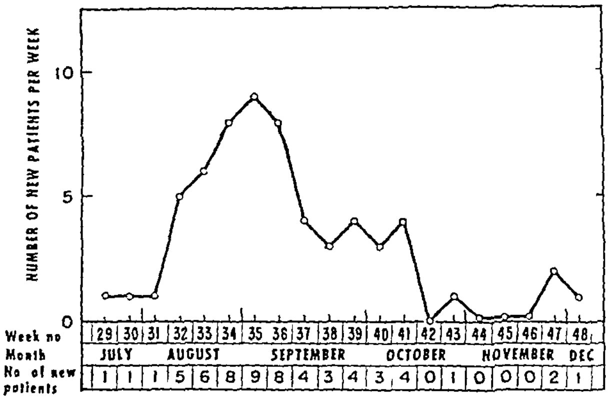

Fig 1 —Seasonal pattern of Coxsackie B5 aseptic meningitis in Minnesota in 1956

The 61 patients with aseptic meningitis from whom Coxsackie B5 virus was isolated had become ill during the seasonal period common to annual outbreaks of epidemic poliomyelitis in Minnesota (fig 1) The first patient who yielded Coxsackie B5 virus became ill on July 17, 1956 The greatest number of new patients per week was nine, between Aug 26 and Sept 1, and the onset of the last illness in this series occurred Dec 1, 1956 The age group most commonly affected (27 of 62) was from 5 to 9 years of age, the age range was from 6 months to 45 years Proved Coxsackie B5 aseptic meningitis was widely distributed through the Minneapolis–St Paul metropolitan area and rural areas, particularly of Faribault, Freeborn, and Waseca Counties in southern Minnesota (fig 2) North to Itasca and St Louis counties, occurrence was sporadic Throughout Minnesota this infection was concurrent with and independent of paralytic poliomyelitis (fig 2)

Illness of the 61 patients yielding Coxsackie B5 virus was characterized by sudden onset of fever with severe headache (49 patients), stiff neck (42 patients), stiff back (11 patients), and leg pains (9 patients) All patients were febrile on admission to hospital, and for at least 56 the temperature was known to have exceeded 100 F (37 8 C) Gastrointestinal symptoms were prominent 28 patients had one or more bouts of vomiting, 11 experienced anorexia, and 8 were nauseated A pleocytosis, predominently lymphocytic, was demonstrated for all of the 52 patients subjected to lumbar puncture Weakness or paralysis of limbs was not a feature of the aseptic meningitis syndrome

Comment

Clear-cut evidence that a single antigenic type of Coxsackie virus was etiological agent of an epidemic of aseptic meningitis in Minnesota during 1956 was provided by (*a*) laboratory isolation of Coxsackie virus immunotype B5 by use of cell cultures from 61 of 113 patients suffering nonparalytic illness during the poliomyelitis season (*b*) concurrent failure to isolate poliovirus from these patients, lack of serologic evidence for concomitant poliovirus infection, and absence of relation between illness and use of polio vaccine, (*c*) demonstration of fivefold or greater increases in titer of antibody to prototypical Faulkner B5 virus in paired serums representative of 9 of 33 patients and presence of homotypic antibody in serum samples from all but one of the remainder, and (*d*) symptoms in patients yielding B5 virus compatible with diagnosis of aseptic meningitis Etiology of the 1956 epidemic contrasts with that of previous seasonal outbreaks of aseptic meningitis, when several immunotypes of Coxsackie B virus were held responsible for clinically manifest infections Coxsackie B5 virus had not been encountered previously in Minnesota

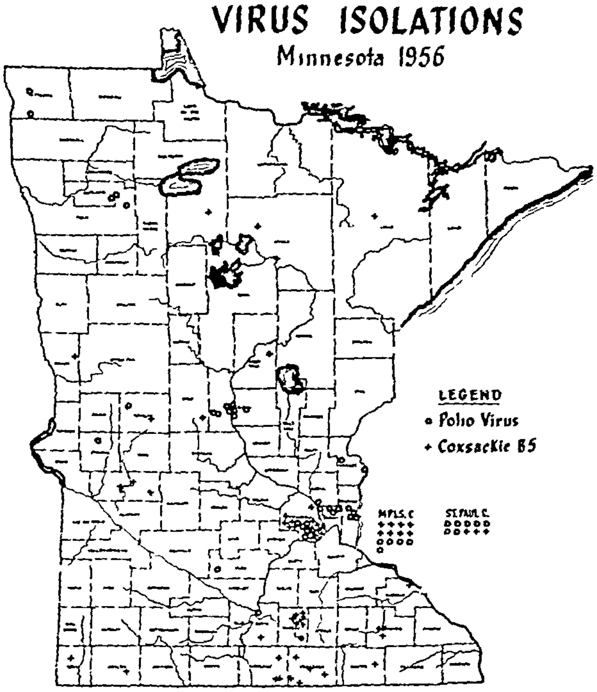

Fig 2 —Geographical distribution in Minnesota of proved cases of aseptic meningitis due to Coxsackie B5 in 1956

Cultures of HeLa cells, cells of other human strains in continuous culture, or cells of monkey kidney in primary culture were equally useful for isolation of wild strains of Coxsackie B5 virus, titers of fecal extracts did not differ significantly as measured by use of the different cells This finding agreed with our earlier experience[4]

Minnesota strains of Coxsackie B5 virus appeared to be antigenically homogeneous Similarly, McLean and Melnick[5] found that strains of ECHO-9 (enteric cytopathogenic human orphan) virus isolated in outbreaks of aseptic meningitis near Cambridge, England, during 1955 and 1956 were antigenically indistinguishable

Clinical features of illness in 61 Minnesota patients infected with Coxsackie B5 virus were similar to those reported by McLeod and co-workers[6] for 17 clinically manifest infections with Coxsackie B viruses and 11 symptomatic infections with ECHO-9 virus[5] On clinical grounds alone, the syndrome exhibited by the 61 patients infected with Coxsackie B virus could not be *distinguished from nonparalytic disease caused by infection with poliovirus* It is noteworthy that illnesses in rural Minnesota from infection with Coxsackie B5 virus occurred in areas free from paralytic poliomyelitis

Results of this study provided further evidence that viral agents other than three known types of poliovirus may cause clinical illness designated as nonparalytic poliomyelitis until the causative agent is recovered and identified The number of etiological agents of aseptic meningitis[7] clinically indistinguishable from nonparalytic poliomyelitis has been found in recent years to include Coxsackie B types 1-4,[8] ECHO viruses types 6[9] and 9,[10] and possibly Coxsackie A7 and other viruses[11]

Summary

Coxsackie B5 virus was isolated from 61 patients in Minnesota who were ill with aseptic meningitis between July 17 and Nov 24, 1956 Titers of antibody in 32 patients confirmed infection with Coxsackie B5 virus Paralytic poliomyelitis was not encountered in rural localities where patients were suffering from aseptic meningitis, and serologic findings showed that these 61 patients were not concomitantly infected with poliovirus

The laboratory work carried out in the Department of Bacteriology and Immunology of the University of Minnesota was aided by a grant from the National Foundation for Infantile Paralysis, Inc, and by contract with the Communicable Disease Center, U S Public Health Service

We are grateful to Dr Paul Ellwood and staff of the Elizabeth Kenny Institute and to physicians on service at University of Minnesota Hospitals for their cooperation and to Dr Robert Barr, medical director of the state health laboratory, for permission to relate results of our laboratory studies to composite epidemiologic findings for the entire state

Hiatal Hernias —Refinements in diagnostic technics, particularly roentgenographic and esophagoscopic, have established hiatal hernias as one of the most common lesions of the gastro-intestinal tract, perhaps second only to duodenal ulcers Marked differences of opinion exist, however, concerning the frequency with which these hernias produce symptoms Roentgenologists, who frequently observe hiatal hernias during the performance of upper gastro-intestinal visualization as an incidental finding, probably minimize the importance of the lesion Conversely, surgeons, often consulted after dangerous complications are apparent, could easily conclude that all hiatal hernias are dangerous Studies of large series of cases indicate that approximately 50 per cent of patients with demonstrable hiatal hernias have significant symptoms This is a relative figure, since the definition of significant symptoms might vary widely and the eventual outcome is unknown—B Blades, M D, and E R Hall, M D, The Consequences of Neglected Hiatal Hernias, *Annals of Surgery,* June, 1956

• It is felt that determination of the prostatic acid phosphatase level has not been of value in diagnosing early carcinoma of the prostate However, as this particular carcinoma becomes more widespread, elevation of the prostatic level does appear Patients with a persistent elevation of the prostatic acid level above 0 7 units per 100 cc, in whom the diagnosis of carcinoma has been made histologically by biopsy, should be strongly suspected of having metastases, even though clinically the disease appears to be localized This finding, therefore, would weigh heavily against surgery, other than for the purpose of palliation

Within recent years considerable enthusiasm has been expressed over use of prostatic serum acid phosphatase levels in the clinical evaluation of patients with carcinoma of the prostate Since the original investigation of Gutman and Gutman [1] in 1938 the total serum acid phosphatase level has been a useful guide in the diagnosis of prostatic cancer Further specificity was given to this enzyme system when Abul-Fadl and King [2] demonstrated a distinct difference between the acid phosphatase of prostatic origin and that produced by the liver, spleen, and red blood cells The hydrolysis of phenyl phosphate by the acid phosphatase enzyme was found to be partially inhibited by the addition of L-tartrate, and it was postulated that the portion that was inhibited was produced by the prostate Subsequently, their work was extended and given clinical application by Fishman and Lerner [3] They reported that all patients with active carcinoma of the prostate demonstrated an elevated prostatic fraction, and, recognizing the possible value of the test in the differential diagnosis of carcinoma of the prostate, they suggested that the prostatic fraction might be elevated in patients exhibiting a normal total acid phosphatase level

Other investigators since have studied this enzyme system, and a multitude of claims and counterclaims have been made for the clinical significance of its levels At present, it is well established that there is an elevation of the serum acid phostatase level in about 80% of patients with untreated metastatic carcinoma of the prostate and this elevation is a reflection of the increased level of the prostatic acid phosphatase

From an extensive study by Cline and co-workers [4] of 1,106 patients with and without prostatic disease, it was apparent that elevation of the prostatic acid phosphatase level above 0 7 units per 100 cc showed a high degree of correlation with prostatic cancer It was also apparent, however, that there was considerable interference from false-positive values, in the order of 5 to 8% in patients with benign prostatic hypertrophy and up to 10% in a group without malignant disease Moreover, they reported finding elevations above 1 5 units per 100 cc only in prostatic carcinoma The sources of error resulting in these falsely high values have been recently reviewed by Ozar and co-workers [5] and include such factors as hemolysis, deterioration of the specimen due to time and heat, previous x-ray therapy, prostatic manipulation, human error, and other diseases associated with elevation of both the serum and prostatic acid phosphatase levels Because of this high incidence of erroneous elevations, many clinicians, failing to understand the reasons for them, became prematurely discouraged with the test and discarded it completely

With the refinement of acid phosphatase determinations and the subdivision of the level into serum and prostatic fractions, it was originally hoped that the use of this more sensitive method would permit earlier diagnosis of prostatic carcinoma Fishman and associates [6] reported that four out of a total of five patients with localized prostatic cancer showed an elevated prostatic fraction in the presence of a normal total serum acid phosphatase level The striking diagnostic implications of this became readily apparent That such elevations may be the exception rather than the rule, however was presaged in the literature much earlier when Woodard [7] found that tissue extracts of prostatic carcinoma contained considerably less acid phosphatase than normal gland tissue This has recently been corroborated by Marberger and co workers [8] In view of this, it would be difficult to postulate the presence of an elevated prostatic acid phosphatase level in all cases of minimal carcinoma In fact one wonders if the disease actually must not be rather extensive before detectable elevations exist

Finally, the significance of serum and prostatic acid phosphatase levels in the long-term management of patients with carcinoma of the prostate must be raised It has been held that the prostatic fraction provides a more sensitive index of prostatic cancer activity than does the total serum level in patients on hormonal therapy and, therefore, is of superior clinical importance

Because our data seemed at variance with some of these previous observations and, yet, because we feel there is definite merit in prostatic acid phosphatase determinations, the present study was undertaken In an effort to establish certain positive criteria for the selection of patients upon whom these difficult laboratory studies should be done, we have chosen to evaluate the prostatic acid phosphatase level as to, first, its role per se as a diagnostic test for cancer, second, its function in detecting local as opposed to metastatic disease, and, third, its superior significance over the total level in the long-term management of patients with prostatic cancer With these questions in

---

From the Department of Urology and the Chemistry Laboratory, Massachusetts General Hospital mind, 88 patients, including 79 with carcinoma of the prostate, have been studied, and it is the purpose of this paper to record our experience in these unsettled areas

Method and Normal Values

The records of the patients for this study were taken from the urologic service of the Massachusetts General Hospital, Boston, during the years 1954-1956 The selection of patients was dictated primarily by the availability of the record and the completeness of the examination Each case listed has been thoroughly investigated All diagnoses have been established by histological examination, and all cases studied have been included

The method of determining the total and prostatic acid phosphatase levels used is that described by Fishman and Lerner It involves the hydrolysis of disodium phenyl phosphate by the serum when incubated for a period of three hours at 38 C, both in the absence and in the presence of 0 2 M L-tartrate The difference found in the amount of phenol liberated represents the inhibition of acid phosphatase of prostatic origin Activity is defined as milligrams of phenol liberated by 100 cc of serum and is usually expressed as King-Armstrong units These properly should be referred to, however, as Gutman units because the analytic procedure now employed is the modification by Gutman and Gutman[9] of the King-Armstrong method for detecting alkaline phosphatase activity In this study, all determinations were done immediately after 10 cc of blood was drawn from the patient in a fasting state, and in each case, except where indicated, the test was done prior to any operative procedure

The normal values for total and prostatic acid phosphatase remain a matter for some debate The upper limit of normal for the total serum acid phosphatase was originally placed at 2 5 units by Gutman and Gutman[8] Later, they revised this figure downward to 2 0 units[9] Since then, a number of other estimates have been made, Fishman and co-workers placed the limit at 5 0 units while Day and co workers,[10] in a comprehensive survey of the problem, arrived at the figure of 3 84 units Mathes and co-workers[11] state that 3 5 units should be the maximum, and we are inclined to agree with this figure As regards the prostatic acid phosphatase level, the upper limit of normal has been taken to be 0 5 units by Fishman and Lerner, 0 55 units by Day and co-workers and 0 7 units by Cline and co-workers[4] We have temporarily accepted this last figure, because of the many determinations in this range we have found in normal subjects Our normal values, therefore, are not grounded in statistical evaluations, rather they are based upon our own clinical impressions, coupled with previously reported laboratory data

Results

For the purpose of analysis and discussion, the patients have been divided into six groups, relating to their clinical status as regards the extent of the carcinoma and, in some cases, to the type of previous therapy We feel that certain trends, which as yet have not been reported, become evident from these groupings, and these are best discussed under the individual groups

Group 1—The first group is composed of patients in whom the carcinoma was limited entirely to the prostate itself, without evidence of local extension or distant metastases The results of the phosphatase studies are listed in table 1

The patients in cases 1 through 7 were ones in whom a minute focus of carcinoma was found after multiple sections were made of tissue removed at the time of prostatectomy The patients in the remaining cases, 8 through 17, were those in whom the disease was more extensive, generally involving more than one lobe It will be seen from the table that only one patient, in case 9, demonstrated an elevated prostatic acid phosphatase level of 0 8 units per 100 cc The levels in the others were well within normal range, and in every case the total acid phosphatase level was normal Thus, from a group of 17 patients with carcinoma found to be limited to the prostate itself by all available clinical, x-ray, and histological evidence, only one showed any elevation of the prostatic acid phosphatase level These data are in disagreement with certain published reports and point to the inadequacy of the test in detecting early carcinoma

16	2 1	0 0
17	1 8	0 3

Group 2—A separate grouping was made of patients with further extension of the disease In these cases, either there has been invasion of the seminal vesicles demonstrated microscopically in the specimen taken during radical perineal prostatectomy, or the clinical impression of seminal vesicle invasion with cancer has been borne out by Silverman needle biopsy of the tumor mass Again, in this group there were no demonstrable distant metastases, and the remainder of the periprostatic tissue seemed free of disease by clinical or microscopic findings or both Table 2 summarizes these results and shows that, of a total of 16 patients, only 1 showed an elevated prostatic acid phosphatase level This was in the patient in case 33 who had a level of 0 8 units per 100 cc and in whom microscopic examination of a section of the biopsy specimen demonstrated tumor extending into the prostatic urethra at the line of resection None of these patients had an elevated total serum level, and the prostatic acid phosphatase levels were generally under 0 5 units per 100 cc

Group 3—Table 3 lists the data from a third group of patients, consisting of those who had distant soft tissue or bone metastases or who had very extensive local disease, with the prostate usually fixed to the pelvic wall None of these patients had any therapy, operative or hormonal, prior to the phosphatase determinations Unlike the patients in group 2, each of these patients demonstrated an elevation of the prostatic acid phosphatase level except for two patients, the patient in case 48, in whom x-ray diagnosis of metastasis was not clearly established, and the one in case 34, who showed a normal prostatic level and elevated total serum level Unfortunately, the determinations were not repeated Two of these 15 patients showed an elevated prostatic level with a normal total serum acid phosphatase level The degrees of elevation of the prostatic acid phosphatase level were quite varied and did not seem related to the extent of disease as demonstrated by x-ray It appears from this, then, that elevations of the prostatic phosphatase levels become manifest only when there has been considerable local extension or distant metastasis of the disease In several of these patients, there was marked elevation of both the total and prostatic phosphatase levels in the presence of nodal but not bony metastases, indicating either that elevations can occur without metastasis to bone or that the metastases were too small to be demonstrated roentgenologically

TABLE 2—*Data on Acid Phosphatase Levels in Patients With Carcinoma of Prostate With Involvement of Seminal Vesicles but Without Other Extension or Known Metastasis After Operation Procedures*

47	Bone metastases	9 8	8 5
48	Extensive local disease and possible spine metastases	1 5	0 2

Group 4—Group 4 comprises the largest single group and consists of patients with carcinoma of the state who previously had hormonal therapy or orchiectomy or both prior to the acid phosphatase determinations Without exception, each of these 21 patients, at the time of the phosphatase studies, was considered to have progressing disease even though there may have been an initial remission due to the endocrine therapy They were hospitalized at this time because of severe bone pain or obstructive symptoms from local recurrence The diagnosis of carcinoma was established at the time of the initiation of therapy by Silverman needle biopsy in all patients who either had undergone bilateral orchiectomy or had simply received estrogen therapy The duration of estrogen therapy is difficult to assess, but in most cases it was continued from the beginning of therapy until the acid phosphatase study was made

The data from this group are summarized in table 4 From a total of 21 patients, only 5 demonstrated elevated serum acid phosphatase levels, and each of these had a concomitant elevation of the prostatic fraction Three of the remaining 16 had an elevated prostatic level and a normal total serum level, and the rest of the group had normal values for both Again, there seemed to be no correlation between the extent of elevation and the extent of the disease as seen clinically One of the patients with the most extensive disease, case 62, showed only an elevation of the prostatic level to 0 9 units per 100 cc with a normal serum level These data therefore suggest that once there is a remission due to hormonal therapy, with subsequent further progression of the disease, there need not be a secondary elevation of the prostatic level Each of these patients was considered to have extensive disease initially, and presumably at least 80% would have shown elevations of the prostatic acid phosphatase level when therapy was begun The fall to normal levels is indicative of successful hormonal control of the disease, but that these levels failed to rise again in 13 out of 21 patients in clinical relapse points to the inadequacy of the test in follow-up of patients through remissions and exacerbations

* TUR transurethral prostatic resection

It has been postulated that the prostatic acid phosphatase fraction is a much more sensitive index of tumor activity than the total acid phosphatase in patients treated by hormonal therapy Our data, however, do not bear this out Clearly, more extensive investigation of a similar group is necessary before any positive generalizations can be drawn Thus far it appears that although determination of the prostatic acid phosphatase level may be a superior test in the initial regulation of patients being treated by hormonal therapy it has not shown a similar superiority in patients who are in relapse, and, in fact, more often than not, neither the total serum or the prostatic levels will show a secondary rise with later progressive disease For the present, it would seem that the serum acid phosphatase determinations alone provide all the useful information available for the clinical management of patients with extensive disease whose conditions have been brought under successful control with hormone therapy or orchiectomy

† TUR transurethral prostatic resection

Group 5—Table 5 summarizes the findings in 11 patients who had been treated for prostatic carcinoma by radical perineal prostatectomy at some time in the past and who had not received endocrine therapy The clinical status of each patient, as adjudged by the same criteria for all other patients, is listed, along with the date of operation and the date and result of the phosphatase determinations Eight of these patients had a recurrence of disease A significant feature of these data appears in the fact that the four patients without evidence of recurrence showed very low prostatic fractions, 0 1 units or less per 100 cc, and it is in patients with previous radical prostatectomy that routine determination of the prostatic fraction may be worthwhile

Four of the eight patients with recurrence had prostatic acid phosphatase levels in the range of 0 2 to 0 5 units per 100 cc, and we hope to accumulate further cases to bear out our presentiment that an elevation of the prostatic level into this range in a patient who had undergone previous radical prostatectomy may serve as a useful danger signal indicating recurrence Our data thus far are merely suggestive

Group 6—The pertinent data from nine patients in whom we found an elevated prostatic fraction without evidence of prostatic carcinoma are listed in table 6 As can be seen, the follow-up studies were done at intervals of from one week to nearly a year Every patient was subjected to the same battery of studies as were all others with suspected carcinoma of the prostate In each case the acid phosphatase levels were determined one or more days after a digital rectal examination, and, in cases 85 and 86, the tests were done prior to the operation Elevations of the prostatic fraction from 0 8 to 2 5 units per 100 cc were encountered in patients with benign prostatic hypertrophy and other diseases These levels returned to normal in five of seven patients after prostatectomy, although, in cases 85 and 86, the elevations persisted It should be emphasized that the elevation in the prostatic acid phosphatase level in the patient in case 83, which was 2 0 units per 100 cc, was found the day after a Silverman needle biopsy, again pointing up the caution that must be exercised in interpreting the levels after prostatic manipulation

These data confirm the suspicion that elevations of the prostatic acid phosphatase level above 0 7 units per 100 cc are possible in patients who do not have prostatic carcinoma and that even elevations above the level of 1 5 units are not diagnostic of carcinoma That these are not merely laboratory errors is supported by the fact that certain of these elevations persisted on repeat determinations They more likely represent false positive values in patients who for unexplained reasons have a transient or persistent elevation of the level of the prostatic fraction Interestingly enough, in two of these patients the elevations did not return to normal after a simple prostatectomy

TABLE 6—*Data on Patients with Elevated Levels of Prostatic Acid Phosphatase and Without Evidence of Carcinoma of Prostate*

Comment

As was pointed out originally, the purpose of this study is to assess the absolute value of the prostatic acid phosphatase determinations in patients with carcinoma of the prostate Fishman and Lerner have offered the theory that the level of the prostatic fraction frequently is elevated in patients with localized carcinoma before the total acid phosphatase rises to abnormal levels, the test, therefore, would be of immeasurable diagnostic aid in evaluating patients with suspected carcinoma Our experience, however, has not borne this out In a group of seven patients with histologically proved minute foci of carcinoma, none showed abnormal elevations of the levels of either the total acid phosphatase or the prostatic fraction Of a total of 17 patients whose disease was limited to the prostate, only 1 had an elevation of the prostatic level, this being to 0 8 units per 100 cc The recognized percentage of false-positive values in this test is in the order of 4 to 8%, and this elevation is considered to be in keeping with this incidence Possibly, however, this patient has undetected distant metastases producing the enzyme, thus far our follow-up period is only two months From these data, we believe that the level of the prostatic fraction does not show elevations in patients in whom disease is limited completely to the prostate Consequently, we feel that the determination of the prostatic acid phosphatase level has not been of value in diagnosing early carcinoma Even as the disease spreads into the seminal vesicles, the prostatic level remains within the normal range As it becomes still more widespread, however, elevation of the prostatic level appears, and, in a group of 15 patients with extensive disease, 13 were found to have elevated prostatic acid phosphatase levels Four of these 13 had a normal total acid phosphatase level and, from our entire group, each patient with a substantial elevation of the prostatic level was found to have disease spread far beyond the confines of the prostate and the seminal vesicles

Several workers[12] have reported a decreased activity of the acid phosphatase enzyme in tissue extracts of prostatic carcinoma as compared with that in normal or hypertrophied glands It has been proposed that the occurrence of metastasis may be associated with the breakdown of barriers that exist in the prostate itself, preventing the escape of acid phosphatase into the circulation, and thus far our clinical evidence lends credence to this theory Qualitative differences may exist between the acid phosphatase enzymes liberated by normal and neoplastic prostatic tissue, and the hope remains that further refinements of our present methods of determination will permit earlier detection of carcinoma

For the present, we do submit the premise that the levels of the prostatic fraction as we are now able to measure them may be of extreme value in patients apparently with localized disease, histologically verified, who are about to undergo radical surgery Because of the natural history of this type of carcinoma, it is possible to have apparently well-localized disease associated with distant, extensive, and otherwise undetectable metastases It has been clearly established that only about one-half of the actual instances of bony metastases can be detected by x-ray examination We are of the opinion that patients with a persistent elevation of the prostatic acid phosphatase level above 0 7 units per 100 cc, in whom the diagnosis of carcinoma has been made histologically by biopsy, should be strongly suspected of having metastases, even though clinically the disease appears to be localized Therefore, these patients are questionable candidates for radical perineal prostatectomy, except for the purpose of palliation to avoid the distressing symptoms of bleeding, obstruction, and bladder irritation

We have not attempted statistical evaluation of these data, because our series is too small to allow valid statistical conclusions Necessarily, the experience of any single urologic service is limited, and considerable time must elapse before a sufficiently large number of case reports accumulate Because of the conflicting reports that have appeared, it becomes imperative that carefully obtained data be reported from other centers in order that investigation of these problems may be carried to a satisfactory conclusion

Summary

Eighty-eight cases, including 79 cases of carcinoma of the prostate, have been studied with reference to the value of serum and prostatic acid phosphatase levels in clinical evaluation Of a total of 17 patients with carcinoma localized to the prostate gland, only 1 had an elevated level of prostatic acid phosphatase and all had normal levels of total acid phosphatase These findings are in conflict with previously reported studies and indicate that in our hands these tests have been of little value in the detection of early carcinoma

Elevations of the levels of the prostatic fraction were found in patients with either very extensive local disease or metastasis, although demonstrable bone metastases were not present in all patients with abnormally high levels We believe that prostatic acid phosphatase levels may be of extreme value in patients with histologically verified carcinoma who are about to undergo radical perineal prostatectomy, elevations above 0 7 units per 100 cc weigh heavily against surgery because of the likelihood of existing distant metastases

Many patients with widespread prostatic carcinoma, after an endocrine-induced remission, will not have concomitant elevations in the prostatic acid phosphatase levels when the disease again becomes progressive, indicating that under these conditions the test is a poor index of tumor activity and is no better than the total serum acid phosphatase level alone The data suggest also that the test may be of value in following patients after radical prostatectomy, slight elevations above the usual very low level may indicate recurrence of disease

NEW SET OF TYPE A INFLUENZA VIRUSES

Keith E Jensen Ph D , Montgomery, Ala

The Public Health Service has been asked to summarize for The Journal *some of the technical information currently available about the new influenza situation The Communicable Disease Center of the Public Health Service maintains a Respiratory Disease Unit in the Virus and Rickettsia Section in Montgomery This unit is responsible for the World Health Organization International Influenza center for the Americas As chief of this unit, many of the observations made concerning the new viruses have been communicated to the author of the following article by investigators in virus laboratories elsewhere, especially those at Walter Reed Army Institute of Research, the School of Public Health in the University of Michigan, and the influenza centers in London and Geneva The earliest data and evidence derived by teams of U S Army investigators have been reported*[1] *Priority and responsibilities for each observation will be established in this conventional manner with publication of completed studies by the individual investigators in suitable journals* —Ed

• *Four major immunological types of virus (A, B, C, and D) are now known to cause influenza, each comprises a completely distinct group Within type A are variants with marked antigenic differences, and groups of these strains comprise sets or families In May, 1957, representative strains from a new set, now termed Far East (FE) or Asian influenza A were isolated from epidemics of influenza in Singapore Only slight antigenic similarity is evident between the FE viruses and other type A influenza strains Serologic diagnosis may be made with either hemagglutination inhibition or complement fixation tests with the new antigens*

The phenomenon of antigenic variation among the viruses which cause influenza has been recognized since the earliest vaccine trials as a basic problem in development of effective control of the disease by immunization[2] Four major immunological types (A, B, C, and D) are now known, and these comprise completely distinct groups of viruses Marked antigenic differences among strains within types A and B have appeared with some regularity Observations made with viruses isolated during the last 24 years indicate that these variations may be summarized as four serologically intersecting sets of type A strains These groups have been referred to as sets or families[3] and previously included the Swine, PR8, and FM1 sets of strains Each has been successively responsible for type A influenza for a period of years Serologic evidence has been obtained that strains of the antigenic nature of the Swine set probably caused pandemic influenza in 1917-1919, remained in circulation 5 to 10 years, and then vanished[4] The first isolates from humans were distantly related to the Swine set, and clearly constitute another group, that is, the PR8 set Type A influenza strains prevalent during the years 1933-1943 were members of this later group, as shown by observations of protective effect of vaccination, antigenic analysis of strains, and seroepidemiologic considerations of strains In 1946-1947 the FMI set or A-prime viruses completely replaced the earlier groups, and the etiological agents of influenza A have been variants within the FM1 set during the last 10 years on a world-wide basis The emergence of a new group of strains has been expected[5] Available evidence strongly indicates that the fourth set of strains has evolved this year and can be expected to replace the FM1 set or A-prime isolates These new viruses were first isolated in May, 1957, from epidemics of influenza in Singapore and are now termed Far East (FE) influenza A[6] This designation is greatly preferred over an A–double prime or similar name

Antigenic Relationships

The modifications of antigenic structure among strains in earlier sets have been followed with interest[3] Early in 1956, virus isolates from Holland, Canada, the United States, England, India, Hawaii, and elsewhere were found to be sharply different from strains circulated in previous years, although they were clearly in the FM1 set This group was called the Dutch 56 by English investigators[7] Strains isolated in Japanese epidemics in December, 1956, were antigenically similar to the Dutch 56 strains Influenza cases which occurred from January through March, 1957, in many

---

From the Communicable Disease Center, Public Health Service, U S Department of Health Education, and Welfare areas of the United States, Europe, and Asia were caused by influenza A viruses closely related to the Dutch 56 strains The FE isolates are distinctly different in antigenic comparisons with all earlier type A viruses Typical results of hemagglutination-inhibition tests with serums from convalescent ferrets and immunized chickens and several strains of types A, B, C, and D influenza are presented in table 1 Although different titers will be obtained with the use of various lines of each virus and serums from other animals or from bleedings at different times after immunization, these results appear to indicate to fair degree the antigenic relationships which exist among these viruses Comparable data have been obtained with serums against several other type A isolates

The isolates have been given designations by influenza centers which indicate the antigenic type and the geographical location of the laboratory which made the isolation or where the case occurred and the year of isolation A number before the year differentiates between isolates and may identify the laboratory responsible for obtaining the virus Thus, strains with the block of numbers 300-400 have been forwarded by the Walter Reed Army Institute of Research Exceptions to this rule are A/Swine/1976/31, which is the virus isolated from pig no 1976 by Dr Shope, and the C/JJ/50, where the letters "JJ" are initials from a patient's name

With the possible exception of a slight reaction between the A/Denver/57 virus and antiserum against the FE isolate A/Japan/305/57, no antigenic similarity is evident between the FE virus and other influenza strains In contrast to these results, titers obtained with the A/Hawaii/56 and A/Denver/57 isolates indicate a very close antigenic relationship These viruses also cross-react to a high degree with 'Dutch 56' viruses and all influenza virus isolations made during the period from January to April, 1957, from many areas of the world The dotted line is to draw attention to the reactions noted between these isolates and the FM1/47 and Mal/54 These results indicate that all four are in a set but that the 1956-1957 isolates may be sufficiently different to alter the formula for a polyvalent influenza vaccine Antigenic intersection between later sets and those of which Swine/31 and PR8/34 are prototype strains can be seen by the low antibody titers No reactions were found between the strains from different types (A, B, C, and D)

The FE viruses are also set apart by results obtained with virus neutralization tests using virus infection in embryonate eggs as the index of serum-virus interaction

At least 20 isolates have been typed as members of the new set, including agents from epidemics in Asia and Europe and sporadic cases in the United States and elsewhere[6b] Although slight differences are noted in cross tests among these viruses, all are closely related antigenically and comprise a new group, or the fourth set of type A influenza viruses

The relationship to the older type A strains is evident from results of complement-fixation tests Both allantoic fluids and membrane extracts from embryonate eggs infected with the new agent have been demonstrated to contain high concentrations of influenza A antigens Data presented in table 2 confirm other observations that the A/Japan/305/57 (FE) strain is a type A influenza virus and that it may be more closely related to A/Denver/1/57 than to A/PR8/34 These results were obtained using a standard overnight fixation method and demonstrate that viral antigens in allantoic fluids gave a more specific reaction than did the membrane extracts which contained a high concentration of "soluble" antigen The membrane extracts had been absorbed with erythrocytes to remove viral particles

‡ Inhibition noted with 2 pools of chicken serums but not with 2 other pools

Growth in Eggs, Tissue Culture, Mice and Ferrets

Strains of the FE set have a host range and in vitro behavior similar to other type A influenza viruses Isolations from throat washings are readily accomplished by standard methods using the chick embryo amniotic sac[8] Allantoic fluids harvested from infected embryonate eggs contain concentrations of 10^8 to 10^9 egg infectious doses per milliliter No notable differences in titers were obtained when eggs were incubated at 35 C rather than 37 C Concentrations of virus as measured by hemagglutination of guinea pig, human, or chicken erythrocytes have been comparatively low (100 to 200), even when the eggs were injected with highly diluted seed or treated cortisone An exception to this observation has been with the recently acquired isolate, A/Formosa/313/57 Eleven-day embryonate eggs inoculated with this strain by the allantoic route and incubated for 48 hours at 37 C have repeatedly yielded pools of allantoic fluids with hemagglutinin titers of 1 800

Fluids from eggs inoculated with strains of the FE set contain virus particles in the filamentous and spherical forms [9] Similar pleomorphism has been demonstrated with many type A strains by electron photomicrography or with the light microscope using darkfield illumination or staining with impregnation procedures [illegible] These observations may account for the usually low hemagglutinin titers obtained and antigenic behavior noted with several of the FE isolates Investigations concerning the significance of these forms in fluids from infected eggs have demonstrated that the long fibers will agglutinate cells and have the antigenic specificity of spherical virus particles, however, they are believed to be infective only at one end [10] Future work with these viruses is indicated to clarify the nature of the various forms

* Infections with strains similar to A/Denver/1/57

It was of interest to find that the FE isolate, A/Japan/305/57, would agglutinate sheep erythrocytes After observations in complement-fixation tests with the virus in allantoic fluids as the antigen, comparative hemagglutination titrations were carried out with 1% suspensions of sheep erythrocytes and 0 5% chicken red blood cell suspensions at 4 C and room temperature At either temperature this virus in allantoic fluids diluted in the usual phosphate-buffered saline solution caused the formation of the typical patterns with both sheep and chicken cells in titers of 1 100 In contrast, the several other type A strains isolated in previous years did not agglutinate the sheep cells In this respect the FE isolate behaves more like type B strain Lee/40, which also agglutinated sheep cells at both temperatures The significance of these observations is not yet clear Although it has been suggested that the strength of the virus-cell bond varies with strains of virus and the species of animals from which the erythrocytes are obtained,[11] further work must be carried out to permit additional speculation

Very limited information has been obtained concerning the growth of FE viruses in tissue culture, mice, and ferrets Virus in allantoic fluids from infected eggs will multiply in monolayer monkey kidney cultures as seen by an increase in hemagglutinin infectivity and slight cytopathogenic changes The concentration of virus produced is similar to that found with many egg-adapted type A strains with hemagglutinin titers in the 10-100 range [12]

The new viruses also grow in mice and ferrets after intranasal inoculations Characteristic lung consolidation was found in mice 3 to 10 days after they were given allantoic fluids containing 10^6 egg infectious doses of any of several FE isolates The viruses have been maintained by several lung-to-mice transfers, however, after five passages lesions were no longer noted, indicating that many of the pathological changes in the first mice were probably due to toxicity, as seen with other influenza viruses [13] Studies concerning the virulence of these viruses are being continued

Serologic Behavior in Laboratory Tests

It was early recognized that many of the FE influenza isolates were very sensitive to nonspecific inhibitors in heated serums which are not antibody and therefore interfere with interpretation of results from hemagglutination-inhibition (HI) tests Furthermore, the treatment of serums with trypsin, periodate, or Vibrio cholerae extracts [8] did not remove these troublesome inhibitors Two of the isolates, A/Japan/305/57 and A/Formosa/313/57, were not sensitive, however, and a majority of the tests have been carried out with these strains Lines of these viruses established by transfers in ferrets and mice and subsequently in eggs appear more capable of combining with antibody than those which have been carried only in eggs but have a greatly increased sensitivity to nonspecific inhibitors [14]

These considerations make it difficult to draw conclusions from data derived by HI or virus neutralization tests Future studies utilizing complement-fixation, serum antibody absorption, or antibody-virus precipitation methods may demonstrate a closer antigenic relationship between the FE viruses and earlier type A strains

* Reciprocal of highest dilution giving positive pattern test with 0 5% suspension of chicken erythrocytes

† Conventional tests using overnight incubation at 4 C and pooled serum from persons convalescent from A infections in March 1957

It has been reported [15] that serum obtained from people in Holland in the age range 70 84 contained antibody against the FE strain Rises in these antibody titers were found in this group after injection of type A vaccines prepared with strains isolated since 1933 This observation is of particular interest because it suggests that viruses prevalent during the pandemic of 1889 contained antigens shared with these most recent A strains, which would be similar to interrelationships demonstrated with the Swine, PR8, and FM1 sets of strains[16] Although serums taken from people of similar age groups in Alabama,[12] Washington, D C,[17] Michigan,[18] and Missouri[19] did not contain inhibiting antibody measurable with FE viruses, additional tests with comparable postvaccination serums and other lines of FE viruses are indicated Studies of this nature are being continued

Antigenic Potency

The evidence is firm that the production of antibody stimulated by injections of preparations containing killed influenza viruses is correlated with immunization against the disease[2] Vaccine specifications have been on the basis of viral concentrations determined by chicken cell agglutination (CCA) activity Early results of studies with the prototype strain A/Japan/305/57 by six vaccine manufacturers in the United States indicated that products containing more than 200 CCA units per milliliter would be difficult to obtain[20] Results of studies by the commission on influenza, Armed Forces Epidemiological Board,[21] with previously isolated A viruses have made it clear that an antigenic mass represented by 750 to 1,000 CCA units was most effective The lower specification of 200 units for military and civilian uses[22] is governed by the practical consideration of the yields obtained in experimental lots by vaccine manufacturers with the A/Japan/305/57 virus

There is reason to believe at this time that considerably more antigen is contained in preparations of this strain than the CCA titer indicates Chickens immunized with allantoic fluids which contain about 50 CCA units have responded by producing antibody measured by HI tests in titers as high as 1 800, which is in the range obtained with greater concentrations of immunizing fluids containing previously isolated A viruses[23] When allantoic fluids were titrated by complement-fixation methods a much higher concentration of antigen was measured than with similar allantoic fluids from eggs infected with other type A viruses Representative results of these tests are presented in table 3 It will be noted that, although the hemagglutinin titers were lower with A/Japan/305/57, the highest complement-fixation antigen concentrations were found with this strain Failure of the PR8 strain antigen to fix complement with antibody in these serums indicates the degree of specificity which may be encountered when serums from young age groups are used This is in keeping with previously recorded observations concerning age-specific antibody[24] In view of these results and the other considerations additional studies are under way to assess the value of complement-fixation titers as a means of indicating antigen concentration and potency of influenza vaccines[25]

Several studies have been initiated to determine the minimal CCA dose of the A/Japan/305/57 strain necessary to elicit antibody in groups of humans At least three methods of virus concentration and vaccine manufacture are in use, and representative preparations have been made available by several pharmaceutical companies for these tests in adult civilian and military populations Early results[26] have indicated that antibody production can be stimulated with this virus

Serologic Diagnosis

The earliest tests[27] demonstrated that comparatively low antibody titers were found in serum from patients convalescent from infection with the FE viruses This may be due to the behavior of these strains in HI tests or, more likely, to the nature of antibody response when a new antigen is encountered[21] It is evident that serologic diagnosis can be made with both HI and complement-fixation test methods[28] However, several cases not detectable when the Japan/305 virus was used in HI tests were found by complement-fixation tests with that virus in allantoic fluid or membrane extracts containing soluble antigen[12] Previous experience has indicated that serologic diagnosis is more often made when both HI and complement-fixation tests are carried out rather than either one[21]

Availability of Materials and Information

Diagnostic serums, antigens, and seed viruses have been sent to approximately 100 laboratories in the Americas which collaborate with the World Health Organization Influenza Program Other interested laboratories are urged to join the network and offer their assistance Any competent laboratory will be supplied materials and information concerning the laboratory aspects of influenza by the center upon request

Dr C C Dauer, in the National Office of Vital Statistics, Washington, conducts the Influenza Information Office for the WHO Influenza Program in the United States, and Dr A M-M Payne, in the WHO offices at Geneva, coordinates the world-wide program Dr Dauer publishes information in the weekly Morbidity and Mortality Reports and should be contacted concerning pertinent clinical and epidemiologic observations

Summary

The influenza now occurring in sporadic cases or epidemics in many areas of the world is caused by viruses of type A Results of antigenic analyses of several of these isolates have made it clear that vaccines should be modified to contain a representative of this new set of variants Laboratory diagnosis can be established by serologic identification of agents isolated from throat washings and by complement fixation and hemagglutination-inhibition tests with paired serums from suspect cases Diagnostic reagents including antigens and typing antiserums have been made available to state health officials and to many laboratories which are cooperating with the Influenza Program of the World Health Organization Vaccine potency tests are in progress, and preliminary results are encouraging

INFLUENZA

LeRoy E Burney, M D , Washington, D C

• *The situation with respect to Asian influenza is unique in that the causative virus has been isolated before the disease itself appeared in the United States Intensive study of past experience makes it seem probable that this disease will continue to spread during the rest of the summer but will not be highly epidemic in the United States until fall or winter, when outbreaks are anticipated Although it is impossible to make any firm predictions at this time, it is unlikely that the virulence of the infection, as manifested in case mortality rates, will be higher in the later outbreaks The present epidemic, with its rapidity of spread and high attack rate, is sufficiently unusual to press for immunization against the new virus As a properly constituted vaccine is the only preventive, its use should be encouraged as soon as it becomes available*

During recent weeks the eyes of the medical profession of the United States have been on the influenza epidemic which swept through the Far East Thus far only sporadic outbreaks have occurred in this country, and have not in themselves offered a serious problem

The important consideration, however, is what will happen during the fall and winter months The distinct possibility of an influenza epidemic in the United States this coming winter cannot be ignored Experts in the field say there is little question that we will have an epidemic in this country sometime during those months In view of this, it seems appropriate to review the current situation, with some dwelling on the lessons learned from the past[1] so that we can be better prepared to meet any eventuality

Historical Aspects

Outbreaks of influenza have attracted considerable attention from many outstanding physicians during centuries in which severe disease and high mortality were commonplace The disease has been known through the ages under a variety of names—the jolly rant, gallants disease, the fashionable illness, and more recently as the flu, or the virus—none of which carry a particularly ominous note

Certain characteristics of the illness distinguished such occurrences from other contemporary disturbances of the day, among which were the sudden appearance and the widespread involvement of all ages and kinds of people

The great similarity in many of the clinical descriptions is also evident Of the extensive epidemic of 1557, T Short relates, as quoted by Francis, 'it began with a roughness of the jaws, small cough, then a strong fever, with a pain of the head, back and legs, some felt as though they were corded over the breast and had a weight at the stomach, all of which continued to the third day at the farthest, then the fever went off with a sweat, or bleeding at the nose In some few, it turned to a pleurisy, or fatal peripneumony "[1] With limited variations this description is met again and again and remains virtually unchanged to the present day

Another prominent characteristic of this illness which has been recorded since the time of the first real pandemic in 1580 is low mortality[2] The single exception to this was in the pandemic of 1918, which will be discussed in further detail

The first epidemic with origin in America was described in 1758 Again the high morbidity and low mortality feature was in evidence Asia and Europe were hit with a pandemic in 1782 Many observers noted the tremendous incidence of the illness, with its peak in May in England, and, while the mortality was

---

Surgeon General, U S Public Health Service, Department of Health, Education, and Welfare low, frequent complications were described. Herpes, erysipelas, sore throat, and pulmonary disease were mentioned repeatedly. Also pointed out at this time was a striking difference in attack rates at varying ages. Young children and older people were less often affected than the middle-aged group. More women than men were said to escape.

In the 19th and 20th centuries, recurrences were highlighted by the pandemics of 1890 and 1918. The pandemic of 1918-1919, which swept over nearly every continent and island of the globe, has been described as one of the great human catastrophes of all time.

Our interest in the happenings preceding the 1918-1919 holocaust are reawakened in view of the unusual features accompanying the current epidemic of Asian influenza. In January, 1916, influenza was reported to be epidemic in 22 states but was described as a mild type of illness.

As early as December, 1917, influenza was prevalent in Camp Kearny, California, and in other Army camps in January, 1918, but the disease was said to be mild. In the spring, localized outbreaks occurred in the civilian population of the United States and mortality from pneumonia rose sharply in certain cities. Mild epidemics of influenza were reported in various localities in Western Europe in April and May of 1918, and in June and July more extensive outbreaks occurred in Great Britain and in Europe, China, India, the Philippine Islands, and Brazil. In these countries, mortality rose moderately.

During August, 1918, epidemics of influenza were reported in Greece, Sweden, Switzerland, Spain, and the West Indies, and late in the month it appeared almost simultaneously in Camp Shelby, Mississippi, and Boston. In September, it appeared in rapid succession in other cities and Army camps along the eastern seaboard and the Gulf of Mexico and spread rapidly westward across the country. By October, the epidemic had involved the entire United States except for a few isolated areas. The interval between the peaks of the epidemic in Boston and in San Francisco was about four weeks, and the peaks in the number of deaths usually were reached within about one month after the beginning of the epidemic in a community or area. In some areas there was a recrudescence of the epidemic in January and February, 1919, which was most marked in the cities where the autumn epidemic was less severe. Thus the influenza epidemic of 1918-1919 was characterized by a relatively mild phase in the spring of 1918, an explosive outbreak with high mortality in the fall, and a third phase or recrudescence early in 1919.

One distinct characteristic of the 1918-1920 pandemic was the extraordinarily high mortality in young adults. The greatest amount of mortality in epidemics prior to and subsequent to 1918-1920 was found in children under 1 year of age and in persons aged 65 and over. About 90% of the men in military service in World War I were young adults between 20 and 35 years of age. Consequently, the armed forces were seriously affected, as were the same age groups in the civilian population. In the Army over a million men were hospitalized for influenza and pneumonia, and of these there were more than 44,000 deaths. There were some 5,000 deaths among Navy personnel.

It has been estimated that there were 20 million cases of influenza and pneumonia in the United States in 1918-1919, with approximately 850,000 deaths. The latter figure includes deaths reported in the military.

The excess in the death rates over the "expected" in 1918-1919 was 598, 92% of which was caused by influenza and pneumonia. In recent years mortality from all causes has not shown a marked rise during influenza epidemics, and deaths attributed to influenza and pneumonia have been increasingly fewer in number. The principal impact of influenza epidemics since 1940 has been an excess of deaths from causes other than influenza and pneumonia, such as heart disease and other chronic diseases. As expected these deaths occur in the older age groups.

Little is known of the true prevalence or incidence of influenza in recent years because reporting of individual cases is unreliable. The disease cannot be clinically differentiated from other types of upper respiratory infections which may also be occurring during an epidemic of influenza, and it is not practicable to obtain laboratory diagnosis of all suspect cases. Absenteeism rates in schools, industries, or other working groups may rise, but such indexes are more useful in alerting health officers to the possibility of an influenza epidemic than in providing figures on incidence.

The virus of human influenza was isolated by Smith, Andrewes, and Laidlaw in 1933 and 1934 after intranasal instillation of throat washings in ferrets. Since that time several strains and types of influenza virus have been isolated, and from materials from patients in 1932 and later years the predominant type of virus has been determined.

Obviously studies prior to 1933 were largely descriptive of the nature of the outbreaks, including explosiveness, extent of the epidemic in terms of death in excess of normal seasonal expectancy, cases reported to health officers or estimated from household surveys immediately following the epidemic, time covered by the outbreak, regions or states where the epidemic was first noted, and the time and direction of its spread.

Since 1948, the Influenza Study Program, which is sponsored by the World Health Organization, has maintained a system of reporting specific diagnoses of influenza in the United States, Canada, South America, and Europe. Information concerning the specific diagnosis of influenza from approximately 40 collaborating laboratories located in universities, hospitals, public health services, and military installations is sent to the Influenza Information Center in the National Office of Vital Statistics. This information in turn has been published in weekly reports and sent to interested individuals in this country and abroad.

Etiological Aspects

Three immunologically distinct types of influenza virus have been identified (A, B, and C) and within type A are some four serologically intersecting groups of type A strains These groups have also been referred to as sets or families Each has been successively responsible for type A influenza for a period of years Serologic evidence has been obtained that strains of the antigenic nature of the swine set may have caused pandemic influenza in 1917-1919, remained in circulation 5 to 10 years, and then vanished except in swine Such viral isolations have made it possible to recognize the cyclic nature of certain strains of influenza virus as well as to chart the course of an epidemic

In the United States during the period 1933-1943 combined clinical, epidemiologic, and microbiologic studies have revealed six definite epidemics of influenza A In 1947 A-prime viruses completely replaced the earlier groups and the etiological agents of influenza A have been variants within the A-prime set during the last 10 years on a world-wide basis In May of this year a new strain of A-prime virus now termed the Asian influenza A–virus was isolated and has been found to be responsible for the current epidemic

Influenza B virus has been responsible for a number of epidemics, the first of which occurred in 1936, which recur at longer cycles than influenza A In both 1936 and 1940 influenza B occurred early in the year and influenza A in the late months Influenza C is described as a virus in search of a disease, despite serologic studies demonstrating it to be a widespread infection

History has taught us that the same virus can be responsible for apparently sporadic, limited epidemic, or pandemic occurrences of influenza and that they may, in reality, represent stages in the development by the virus of epidemic properties during its adaptation to the human population It is pointed out by the Commission on Influenza that, while the clinical and epidemiologic characteristics of epidemic prevalences may be quite similar, the problem of waves and recurrences is a complex one, involving viruses of different immunologic character It seems that similar viruses have been responsible for the otherwise characteristic but unidentified experiences both before and after 1918 Interestingly enough, no particular bacterial agent has been a consistent, or even frequent, accompaniment of these viral outbreaks The conclusion is, then, that influenza virus was the decisive factor of 1918, producing a severe primary damage to the respiratory epithelium and creating a medium in which various bacterial agents could become implanted and produce the multiform pictures which were actually observed

Present Epidemic

The current epidemic of influenza was first reported in Hong Kong and Singapore during the latter half of April, 1957 Then, in rapid succession, epidemics occurred in Taiwan, the Philippines, the Malayan States, Japan, India, and other areas

Army medical teams investigating the early epidemics noted that the isolated virus appeared unusual in laboratory tests and sent the virus to the United States for antigenic analyses These analyses demonstrated that the virus is type A, but is antigenically different in the hemoagglutination inhibition test from any previously known type A strains Animal antiserums prepared against type A strains did not inhibit or neutralize the new variant, and no protective antibody could be demonstrated in serums from human beings repeatedly vaccinated with previously prevalent type A virus Information to date suggests that little protection against the new virus is gained by previous vaccination with existing influenza vaccine

Laboratory confirmation of sporadic outbreaks of Asian influenza in both military and civilian populations has been received from several sections of the United States Beginning June 2, a series of influenza outbreaks were reported among ships which had been berthed in Narragansett Bay, Newport, R I The means of introduction of the virus to this population could not be ascertained, and spread of the epidemic was erratic Subsequently infections with Far East strain influenza virus have been reported in San Diego, Monterey, Davis, and San Francisco, Calif , Cleveland, Lexington, Ky , Valley Forge, Pa , Salt Lake City, and Grinnell, Iowa

An interesting example of how the virus has spread in the United States is illustrated in the appearance of illness in California early in June, apparently introduced from returning visitors from the Far East From California the illness spread inland initially to Iowa, Montana, and Utah Further seeding of the virus was accomplished in July by travelers originating in Iowa and California The highest attack rates (70%) have occurred among recruits in the military services The other large outbreaks reported in the United States have been predominantly in groups of young people living, or brought together, in environments that favor the spread of infection To date there has been little variation in severity of the illness and but two deaths have been reported in the United States resulting from complications of influenza

Clinical and Public Health Aspects

The experience in Asia and in the United States since the new type of virus was introduced provides no basis for predicting an increase in severity of infection in the coming fall and winter or during the next year or two The present concern arises largely from the possibility that a more virulent variant of the Asian type may emerge The severity of the 1918 influenza epidemic is believed to have been due to some such mutation which exposed the population to a virus or viruses with antigenic properties radically different from those strains to which they had been previously exposed

Influenza is one of several acute infectious diseases involving the upper respiratory tract that may occur in epidemic form Such infections as adenovirus (APC-ARD), exudative pharyngitis, the common cold, and others cannot be differentiated from influenza without appropriate confirmatory laboratory tests An outbreak of influenza may occur simultaneously with one of the other respiratory infections However, influenza usually spreads more widely and more rapidly and its presence may be suspected when an epidemic shows this characteristic

Clinically influenza is usually characterized by abrupt onset, prostration, temperature as high as 104 F (40 C), headache, myalgia, cough, and sore throat X-ray examinations of the chest usually show no abnormal findings Leukopenia is common in uncomplicated cases The febrile period usually lasts three to five days, following which the patient may complain of extreme weakness for several more days

In laboratory diagnosis of individual cases, the virus may be isolated from secretions of the nose and throat taken early in the course of the illness The procedure consists of inoculating chicken eggs which have been incubated for about 10 days and recovering the virus in the fluids of the embryonic sac

Paired specimens of blood, one taken in the acute phase and the other 10 days to two weeks later, may be used for serologic tests A fourfold or greater rise in antibody titer is regarded as an indication of influenza infection Since neither of these laboratory procedures can be completed while the patient is still acutely ill, they are of little value to the physician in prescribing treatment Such tests are necessary, however, to confirm the presence or absence of influenza in a community

Even when considered mild in terms of fatality, influenza epidemics cannot be regarded as innocuous Illnesses usually are prostrating for two or more days and are often followed by a period of lassitude and weakness In an epidemic, medical care facilities may be temporarily overtaxed, attendance in school interrupted, and the entire economy disrupted by absenteeism in all types of industries, some of which are in critical areas

Immunological Aspects

The isolation of specific types and strains of influenza virus has explained substantially what was formerly believed to be the brief immunity conferred by an attack and has also created critical problems in the development and production of effective immunizing agents Type A was first isolated in 1933 and, in 1940, type B was discovered and found to have no serologic relationship to type A Neither virus stimulates the production of antibodies against the other Thus it became clear why some individuals had second attacks of influenza within a year or two The later identification of variants of type A further clarified the question of repeated attacks, since some of these variants had quite different antigenic components Serologic tests conducted in recent years indicate, however, that an attack of influenza confers a relatively long-lasting immunity to the specific virus involved, as well as to homologous or closely related strains The introduction of new variants increases the possibility of repeated attacks

Vaccines of high potency will stimulate the production of antibodies against strains of influenza virus that have been used in their manufacture, as well as against closely related strains Even when antibodies cannot be detected by serologic tests of vaccinated persons there is reason to believe that such vaccines afford some protection against natural infections When a variant appears whose antigenic structure is widely different from that of previously isolated viruses, a vaccine which has been satisfactory hitherto may be relatively ineffective against the new strain This happened in 1947 when the A-prime influenza virus was identified The same problem confronts manufacturers of vaccine today with the introduction of the new Asian virus If a variant can be discovered and incorporated into vaccine shortly after it has emerged, the vaccine can often be used effectively in reducing the number and severity of illnesses caused by the new virus

Influenza vaccines have been used most extensively in special population groups such as military personnel, schools, and certain employee groups Studies in the military reveal that a properly constituted vaccine is 70% effective under epidemic or endemic conditions and that reactions to the vaccine are quite rare Individuals known to be sensitive to egg are not given the vaccine, since virus is grown in embryonated eggs

The manufacturers of vaccines have been able to produce a satisfactory monovalent vaccine containing the Asian strain They are currently working to produce this vaccine on a large-scale basis

Present Considerations

Thanks to alertness of epidemiologic and laboratory workers in the military, an isolation of the causative virus has been made prior to the appearance of influenza in the United States The uniqueness of this situation is appreciated when we realize that for the first time in history we are in the fortunate position of being ahead of an impending epidemic of influenza

On the basis of past experience it seems probable that influenza will continue to spread for the remainder of the summer months but will not be highly epidemic in the United States until fall or winter, when outbreaks may be anticipated Although the disease will probably be mild, there is always the outside possibility of a repeat of the 1918 epidemic There is a further possibility that the virulence of the infection as reflected in case-mortality rates will increase Even though these are still only possibilities, any preparations which need to be made to meet these eventualities must be accomplished now After a pandemic starts it will be too late

The world-wide influenza study program under the auspices of WHO, which for the most part is mainly with the Public Health Service in the United States, has been functioning during the current alert and is being strengthened by a greater number of laboratories and observers both in this country and abroad

At the invitation of WHO, a plan for investigation of influenza outbreaks in foreign countries has been developed by the Influenza Commission of the Armed Forces Epidemiologic Board This operation will utilize personnel on the commission, certain investigators from universities, and members of the uniformed services In this way more detailed field information can be obtained about these epidemics than is available from the usual sources In particular the teams will be interested in determining (*a*) the properties of the virus, (*b*) complete clinical descriptions, (*c*) whether a bacterial component is associated with the illness, and (*d*) epidemiologic aspects

The American Medical Association has already announced a program designed to offset the severe strain placed on medical personnel when so many people suddenly become ill

Finally, in recent years the nature of influenza in the United States has not warranted the use of influenza vaccine except on a group basis to minimize absenteeism or in so-called priority groups However, the present influenza epidemic, with its rapidity of spread and high attack rate, is sufficiently unusual to press for immunization against the new strain of influenza virus As a properly constituted vaccine is the only preventive for this disease, the Public Health Service with the Association of State and Territorial Health Officers and the American Medical Association plans to promote the use of the vaccine as soon as it becomes available To accomplish this we plan to embark upon an educational and promotional campaign to encourage all persons who want it to seek influenza vaccine on a voluntary basis Any such campaign must be conducted in an orderly fashion to avoid confusion and hysteria in the public and will call for the combined efforts of all of us

Summary

Influenza has been known for centuries under a variety of names, but, except for the pandemic of 1918, the illness was regarded lightly For the past 25 years it has been possible to incriminate certain strains of type A virus and type B virus as causative agents of cyclic outbreaks of influenza

The current epidemic in the Far East and the sporadic outbreaks in the United States and elsewhere are caused by a new strain of type A virus popularly known as the Asian strain There is a distinct probability that the current influenza epidemic will increase and develop into pandemic porportions by late fall or winter Also there lurks the possibility of an increase in virulence of the infection as reflected in case-mortality rates A properly constituted vaccine containing the new strain of type A virus represents the only preventive tool at our command

Influenza vaccines have been proved effective and safe in controlled studies conducted by the military The Public Health Service, in cooperation with the State and Territorial Health Officers and the American Medical Association, will stimulate and promote a nationwide voluntary program of vaccination against the prevalent strain of influenza

CLINICAL NOTES

ON PERIPHERAL THROMBOPHLEBITIS

ITS OCCURRENCE AS A PRESENTING SYMPTOM IN MALIGNANT DISEASE OF PANCREAS, BILIARY TRACT, OR DUODENUM

Stanley O Hoerr, M D
and
Jack R Harper, M D , Cleveland

Trousseau,[1] in 1856, noted that thrombosis of peripheral veins may be the first clinical indication of the presence of a malignant tumor in some part of the body This observation has had such recent confirmation as the study of Woolling and Shick [2] They reported 15 cases of carcinoma that had been unrecognized until after the patients sought medical aid because of symptoms referable to thrombophlebitis The association of venous thrombosis and carcinoma of the pancreas was carefully investigated in autopsy material by Sproul,[3] who found thrombosis of one or more veins in 14 of 47 patients with carcinoma of the pancreas and in 9 of the 16 patients with carcinoma restricted to the body or tail—a very high incidence

Generations of medical students have been taught, on the basis of these and similar studies, that peripheral thrombophlebitis as a presenting complaint is suggestive of malignant disease in organs of the upper abdomen, particularly the pancreas We, on the other hand, have been impressed with the infrequent clinical association of the two diseases (as opposed to findings at autopsy) To test our clinical impression, we reviewed the case histories in a personal series (S O H) of 100 consecutive patients who had carcinoma The site was the head of the pancreas in 38 cases, the body and tail of the pancreas in 21 cases, the ampulla of Vater in 13, the common bile duct in 13, the gallbladder in 9, and the duodenum in 6

From the Department of General Surgery of the Cleveland Clinic Foundation, and the Frank E Bunts Educational Institute Dr Harper is a Fellow in the Department of General Surgery, the Cleveland Clinic Foundation

In the 100 case histories, we found only one case of peripheral thrombophlebitis, it was the presenting symptom in a patient who had carcinoma of the head of the pancreas One case of thrombosis of the hepatic veins in association with carcinoma of the tail of the pancreas was found at autopsy The only other case suggesting previous venous difficulty was that of a patient who had carcinoma of the body of the pancreas and who had had stasis dermatitis of the legs (present for years) recorded as an incidental finding

After determining this low incidence of thrombophlebitis, we reviewed 46 cases in which the primary diagnosis was peripheral thrombophlebitis They were random case records obtained from the record room, not a consecutive series, and, as such, are subject to the limitations of all nonconsecutive series One case record from the personal series already mentioned was included, the patient had carcinoma of the head of the pancreas Carcinoma or other malignant disease was disclosed in 7 (15%) of the 46 cases In these seven, the site of the malignancy was the prostate in two cases, the lung in one, the liver (primary) in one, and the pancreas (our case) in one There was one case of lymphosarcomatosis and one of chronic lymphatic leukemia

In our consecutive series of 100 cases of biliary, pancreatic, and duodenal carcinoma, the low incidence (2%) of thrombophlebitis possibly could be related in some obscure fashion to the type of patient who receives treatment at a private clinic Or it may represent a true index of the frequency with which the conditions are associated, as seen by the clinician On the other hand, an incidence of 15% (7 of 46 patients) of malignant disease in some part of the body in patients whose presenting symptom is thrombophlebitis reaffirms the original observation of Trousseau

Comment

Patients with carcinoma of the pancreas, gallbladder, bile duct, or duodenum, as seen by the clinician, do not have a high incidence of peripheral thrombophlebitis, but patients with spontaneous thrombophlebitis do have a significant incidence of malignant disease

HIGH ACID PHOSPHATASE LEVEL INDICATING GAUCHER'S DISEASE IN PATIENT WITH PROSTATISM

Lester R Tuchman, M D

and

Moses Swick, M D, New York

While no laboratory test is pathognomonic of a single disease, the one regarded as most nearly approaching this aim is the determination of the serum acid phosphatase level Since the work of Gutman and Gutman,[1] a pronounced elevation of the serum acid phosphatase level has been considered indicative of metastasizing carcinoma of the prostate One of us and co-workers[2] have pointed out that the serum acid phosphatase level is elevated in Gaucher's disease (lipid histiocytosis of kerasin type) and described eight patients with values ranging from 4 0 to 11 7 units per 100 cc, of whom seven had values of 7 units or over Elevation in one case of Niemann-Pick disease (lipid histiocytosis of phosphatide type) has been described in the Scandinavian literature[3]

The following case of a 68-year-old man seen by one of us (M S) for classic symptoms of prostatism is reported The finding of a serum acid phosphatase value of 10 3 Gutman units per 100 cc led to the presumptive diagnosis of carcinoma of the prostate with metastases When the clinical findings, the results of punch biopsy, and the improvement of the symptoms made the diagnosis untenable, the recent finding of one of us (L R T), Suna, and Carr was recalled[2] A sternal marrow aspiration was done, and the diagnosis of asymptomatic Gaucher's disease, which was hitherto unsuspected, was made

Report of a Case

A 68-year-old man was admitted to the urologic service of Dr G D Oppenheimer at the Mount Sinai Hospital, New York, with a chief complaint of dysuria and nocturia of two months duration He had always been well until one year previously, when he had a brief episode of dysuria Two months before admission, he began to experience dysuria and nocturia that reached the frequency of three times nightly One of us (M S) saw the patient in his office and had the patient hospitalized for study because acid phosphatase determinations gave successively levels of 7 0 and 10 3 Gutman units

Physical examination showed the patient to be a vigorous, healthy-appearing man of 68 years of age, who was only slightly disturbed by his physical complaints Except for incipient cataract formation and mild senile emphysema, no abnormalities were found on general physical examination His blood pressure level was 130/60 mm Hg, his chest was clear on fluoroscopy, and the heart sounds were normal No masses were felt in the abdomen The prostate was enlarged to about twice its normal size, but it felt smooth, no nodules being palpated

The laboratory findings included urine with a specific gravity of 1 016 and no albumin or sugar and two to seven red blood cells per high-power field The hemoglobin level was found to be 12 6 Gm per 100 cc, and the white blood cell count was 5 400 per cubic millimeter, with 76% polymorphonuclear cells,

---

From the departments of medicine and urology, the Mount Sinai Hospital

16% lymphocytes 1% eosinophils, 1% basophils, and 4% monocytes The sedimentation rate was 31 mm per hour (Westergren) Sulfobromophthalein (Bromsulphalein) determination showed 2% retention at the end of 15 minutes the urea nitrogen level was 11 mg per 100 cc, and the sugar level in the fasting state was 107 mg per 100 cc The serum total protein level was 8 Gm per 100 cc with 4 6 Gm albumin and 3 4 Gm globulin The result of the cephalin flocculation test was 2+ The cholesterol ester partition was 201/162 mg per 100 cc Two additional determinations of serum acid phosphatase with the phenyl phosphate substrate showed values of 7 4 and 7 4 units per 100 cc Alkaline phosphatase values were 7 2 and 8 1 King-Armstrong units per 100 cc, which precluded the explanation of the elevated acid phosphatase values as being due to nonspecific spillover

A cystogram showed a normal-sized bladder with the floor slightly elevated, and an intravenous pyelogram showed normal urinary tracts bilaterally X-ray examination of the skull the thoracic and lumbosacral spine pelvis ribs and the long bones of the upper and lower extremities showed no evidence of discrete cystic, or blastic lesions

On the patient s admission the majority opinion on the urologic service was that carcinoma of the prostate was the most probable diagnosis this opinion being based upon the age of the patient, the symptoms of prostatism, and the elevated serum acid phosphatase levels The prostate, however was smooth and no nodules were felt therefore a perineal biopsy was performed The tissue obtained was reported as showing fragments of prostatic tissue without significant change and no definite evidence of tumor After a postbiopsy urinary retention the patient s symptoms of prostatism abated completely At this point, while other members of the service puzzled over its significance Dr S A Averbuck and one of us (M S) independently suggested that the elevated serum acid phosphatase levels might be due to Gaucher s disease The hematological consultant did not agree with the idea but after a palpable liver and spleen were demonstrated, he agreed to do a sternal marrow aspiration The aspirate was reported as being a somewhat dilute marrow showing megakaryocytes in adequate numbers and Gaucher cells on the smear

Comment

It is probable that the diagnosis of Gaucher's disease would never have been thought of, in this vigorous, well man who had lived a long life with no significant disability and whose hepatosplenomegaly was so minimal that it was only established after the diagnosis of Gaucher's disease was considered, had it not been for the failure to explain the elevation of the serum acid phosphatase level on the basis of carcinoma of the prostate with metastasis This certainly seemed the reasonable and probable explanation when the patient was first seen, but the complete subsidence of prostatic symptoms, the negative findings on perineal biopsy, and the well-being of the patient, failed to substantiate this opinion Without the sternal marrow biopsy, the case would have remained an enigma The patient could have had a prostatectomy, which would have shown a benign prostatic adenoma, or he would have been watched In either instance, there would have been no explanation for the elevated serum acid phosphatase level It is noteworthy that an extensive x-ray survey of the bones was negative and that no evidence of liver disease was present

An earlier paper by one of us and associates[2] includes the report of the case of a 74-year-old physician, known to have had Gaucher s disease for many years, in whom a serum acid phosphatase level of 8 3 units per 100 cc remained unexplained when the findings at operation and the pathological report revealed a benign prostatic adenoma

Summary

A 68-year old man was suspected of having carcinoma of the prostate because of prostatism and an elevated serum acid phosphatase level The diagnosis, hitherto unsuspected, of Gaucher's disease (lipid histocytosis of kerasin type) was established by sternal marrow biopsy

Pain in Shoulder, Arm, or over the Chest—Osteoarthritis is a common cause of irritation of nerve roots In 1925, Parker and Adson provided one of the earliest descriptions of encroachment by hypertrophic spurs on the spinal foramina, causing irritation of the nerve roots, with symptoms referred to the region of distribution of some of the efferent portions of the particular nerves Bony changes frequently occur in osteoarthritis of the cervical segment of the spinal column These changes are found most often in the lower cervical vertebrae from which emerge the sixth, seventh and eighth cervical nerves It is well to recall that these segments contain a portion of fibers which supply the pectoralis major and minor, the subscapularis and the deeper portion of the latissimus dorsi muscles If the foramina from which these nerves emerge are narrowed, it can readily be undersstood how a patient could have a pain over the pectoral region or the region of the shoulder and arm Occasionally, a patient will have osteoarthritis of the cervical portion of the spinal column and complain of a dull ache largely confined to the region of a shoulder and arm The patient may not complain of pain in the neck but he may have noticed that certain movements of the neck, such as hyperextension, will produce pain in the region of the shoulder, arm or chest However, when a patient complains of pain in the shoulder, in the arm or over the chest, it is well to keep in mind the fact that this pain may be due to osteoarthritis of the cervical vertebra —D J Erickson, M D, Cervical Traction and Other Physical Therapeutic Procedures for Pain About the Neck and Shoulders, *Minnesota Medicine*, June, 1956

COMMITTEE ON MEDICOLEGAL PROBLEMS

MEDICOLEGAL APPLICATIONS OF BLOOD-GROUPING TESTS

Last year the Committee on Medicolegal Problems published a tentative supplementary report discussing the medicolegal applications of blood-grouping tests (J A M A 161 233-239 [May 19] 1956) Because a portion of the report was controversial, comments were solicited from workers in the field These comments have been received and analyzed, and below is the revised and final version of the report of the Committee on Medicolegal Problems, American Medical Association, prepared by a subcommittee consisting of Alexander S Wiener, M D, Brooklyn, N Y, Ray D Owen, Ph D, Pasadena, Calif, Clyde Stormont, Ph D, Davis, Calif, and Irving B Wexler, M D, Brooklyn, N Y—ED

In 1952 a report[1] was prepared by the Committee on Medicolegal Problems of the American Medical Association describing the status at that time of the medicolegal application of blood-grouping tests for the exclusion of parentage and for the examination of stains of blood and secretions The purpose of this supplementary report is to review further developments in the field during the period 1952-1957

Blood Group Nomenclature

One of the most pressing problems at the present time is that of blood group nomenclature This pertains particularly to the important Rh-Hr types, for which two principal methods of designation are in use, namely, the original Rh-Hr nomenclature and the C-D-E symbols The submission to jurists by different experts of medicolegal reports with conflicting symbolisms cannot help but confuse them and shake their confidence in the blood tests Moreover, reports in two different symbolisms require translation from one into the other when comparisons are to be made, there is always danger of error in this process Therefore, the adoption of one uniform nomenclature for medicolegal reports is most desirable

Marked disagreement is prevalent among workers in the field, and while the Committee is prepared to make a firm and unqualified recommendation, a survey of contrary opinion has been prepared and can be found in the section 'Contrary Opinion on Nomenclature Although corresponding to the two systems of designating the Rh-Hr types there are two conflicting genetic theories, the crux of the problem is actually on a serologic level It is most important to distinguish clearly between agglutinogens and their serologic attributes, the blood factors[2] An agglutinogen may be defined as a substance present on the surface of the red blood cells that is differentiated by certain agglutination reactions with diagnostic reagents The blood factors, on the other hand, are those attributes of the agglutinogen molecule (perhaps an arrangement of polar groups, electric charges, and other configurational details on the surface of the molecule) that enable it to combine with antibodies In general, each agglutinogen is characterized by multiple blood factors The C-D-E notations for the Rh-Hr types make no allowance for the difference between a blood factor and an agglutinogen and incorporate the tacit, incorrect assumption that every agglutinogen has but a single corresponding antibody This has led to a number of paradoxes, which have been described in detail elsewhere[3] and need not be elaborated here Indeed, much of the evidence that has accumulated regarding the serology and genetics of the Rh-Hr types refutes the interpretation implicit in the C-D E notations On the other hand, the original Rh-Hr nomenclature presents the data objectively, without committing the user to a preconceived interpretation, which at times may be inconsistent with the actual observations Under these circumstances, the Committee has been obliged to adopt the original Rh Hr nomenclature as the sole nomenclature in the preparation of this report This committee, therefore, recommends that the C-D-E notations for the Rh-Hr types be discarded and that, in approved medicolegal reports, unless and until some other convention is agreed upon, the original Rh-Hr nomenclature be retained as the sole nomenclature for this blood group system (table 1)

In any blood group system, and the Rh-Hr system in particular, one must carefully distinguish among agglutinogens, blood factors, and genes To avoid confusion among these three levels, appropriate provisions must be made in the symbols Therefore, it is suggested that regular-face type be used for agglutinogens and phenotypes, boldface type for blood factors and their corresponding antibodies, and italic type for genes and genotypes This is in keeping with accepted genetic usage This recommendation is approved by this committee and has been adopted for the purpose of this report For purposes of illustration and for its practical value, the heredity of the Rh-Hr types will be briefly reviewed, using the recommended nomenclature

At the present time, four principal Rh blood factors (**Rh_0**, **rh'**, **rh"**, and **rh^w**) and three principal Hr factors (**hr'**, **hr"**, and **hr**) are recognized However, antiserums for only four of these seven factors are readily available for routine clinical and medicolegal work, namely, anti-**Rh_0**, anti-**rh'**, anti-**rh"**, and anti-**hr'** Therefore, this discussion will be confined to the results obtained using these four antiserums (Some workers also routinely carry out tests with anti-**hr"** serum) Ample evidence is now available that there are eight principal alleles determining the heredity of the Rh-Hr types, as distinguished by these four reagents Table 2 lists these alleles and their corresponding agglutinogens, as well as the blood factors that characterize each agglutinogen Table 3 gives the various reactions that may be encountered in actual tests carried out with the four Rh-Hr antiserums It will be seen that there are 12 possible phenotypes, to which there correspond 36 theoretically possible genotypes With these basic data, it is simple to determine which Rh-Hr types can occur and which cannot for any given mating

								Rh Rh	2 4	+	—	—	R^2R^2 or R^2r'
			Rh$_z$	13 4	+	+	—	Rh₁Rh	12 9	+	+	—	R^1R^2 R^1r'' or R^2r'
								Rh$_z$rh	0 2	+	+	+	R^zr R^zR^o or R^or^y
								Rh$_z$Rh₁	0 2	—	+	—	$R R^1$ R^zr' or R^1r^y
								Rh$_z$Rh	0 07	+	—	—	R^zR^2 R^zr'' or R^2r^y
								Rh Rh$_z$	0 0004	—	—	—	$R R$ or R^zr^y
			Rh$_z$^{w}	0 6	+	+	+	Rh₁^{w}Rh	0 6	+	+	—	$R^{1w}R^2$ $R^{1w}r'$ or $R^2r'^w$
								Rh$_z$^{w}Rh₁	0 008	—	+	—	$R^{1w}R^z$ $R^{1w}r^y$ or $R^zr'^w$

* In this table Rh₁ is used as a short designation for Rh₀ Rh₂ is short for Rh₀″ rh$_y$ is short for rh ″ and Rh$_z$ is short for 𝔑h₀ ″

† The reduction in the frequency of type rh as compared with that given in earlier charts can be attributed to recognition of bloods of type 𝔑h₁ (containing Rh₀ variant) which are now included in type Rh₁ instead of rh The agglutinogens 𝔑h₀ 𝔑h₁ and 𝔑h and their corresponding genes $\mathfrak{R}^o$ $\mathfrak{R}^1$ and 𝔑 are not given here because this would serve unnecessarily to complicate the chart by increasing the number of possible genotypes to 91 Also no attempt is made to include certain rare exceptional bloods such as those lacking both factors rh and hr′ and/or lacking both rh and hr″

‡ Based on the estimated gene frequencies $r = 0 38$ $r' = 0 006$ $r'' = 0 005$ $r^y = 0 0001$ $r'^w = 0 00005$ $R^o = 0 027$ $R^1 = 0 41$ $R^2 = 0 15$ $R^z = 0 002$ and $R^{1w} = 0 02$.

§ This table does not include hypothetical genes R^{zw} and r^{yw} which must be extremely rare

Taking into account the 12 possible phenotypes, there are 78 matings to be considered (When the reactions of anti-hr″ serums are taken into account, the number of phenotypes is increased to 18 and the number of matings to 171 A table listing these 171 matings has been published by Wiener[4]) A table listing the 78 matings would require more than two pages Boyd[5] has devised a compact method of presenting the various matings in the form of a 12 by 12 table, and table 4 was drawn up after examining the similar table prepared by Boyd It will be noticed that the phenotypes have been numbered, but these numbers are not intended to be used as a new nomenclature for the Rh-Hr types The phenotype numbers are used merely for compactness in presenting the table, and the key to the numbers is given at the top and side of the chart For example, in the mating Rh₂ × Rh₂ phenotype numbers 2, 3, 5, 6, 8, 9, 11, and 12 appear in the box, which means that parents both of type Rh₂ cannot have children of types rh′rh, rh′rh′, rh′rh″, rh$_y$rh′, Rh₁rh, Rh₁Rh₁, Rh₁Rh₂, or Rh$_z$Rh₁ This is readily verified with the aid of tables 2 and 3, since both parents of type Rh₂ can be carriers of genes R^2, R^o, r'', or r, and not of genes R^1, R^z, r', or r^y, so that all children with phenotypes in which one or more of the latter four genes must be present are excluded The numbers in boldface type indicate phenotypes that, if present in the child, exclude maternity Thus, a type Rh₂ mother cannot have a child of type rh′rh′, rh$_y$rh′, Rh₁Rh₁, or Rh$_z$Rh₁

Contrary Opinion on Nomenclature

The tentative report, upon which the present report is based, called attention to the diversity of opinion that exists with reference to problems of blood group nomenclature, and in an accompanying editorial the hope was expressed that 'workers in the field will limit their views on matters of nomenclature to the

Committee on Medicolegal Problems within the next few months, so that they can be considered in the preparation of the final report " In the tentative report, the Committee found itself unable to define a position compatible with all of the diverse opinions in this field and chose a stand that according to its own lights was sound It is desirable to include in this final report a summary of contrary opinion as it appeared in the replies to the call for comments on the tentative report

TABLE 3 —*Rh Hr Phenotypes and Corresponding Genotypes*

Forty-nine letters were received, of which 43 expressed classifiable opinion on Rh-Hr nomenclature Twenty-one of these were opposed to the recommendation on nomenclature and, for the most part, appeared instead to favor the exclusive adoption of the C-D-E-F system Seventeen were in express agreement with the recommendation that "in medicolegal reports, unless and until some other convention is agreed upon, the original Rh-Hr nomenclature be retained as the sole nomenclature for this blood group system " Five others would retain both the Rh-Hr and C-D-E-F nomenclature The communications received therefore suggest an approximately equal division of opinion on nomenclature

In order to present properly the criticisms received regarding the report, it is necessary first to review the points on which the Committee bases the position it adopted These were as follows 1 There is need for a uniform nomenclature in medicolegal practice 2 The C-D-E-F notation is undesirable because it is based on principles in conflict with established serology 3 The Rh-Hr nomenclature is based on rational serologic and genetic grounds It was suggested, therefore, that unless and until some better nomenclature is developed, it would be well to adopt the Rh-Hr nomenclature for exclusive use in medicolegal practice In the present section of this report an effort will be made to present a synopsis of the views of those who opposed this suggestion The Committee does not identify itself with these assertions

With the eventual desirability of a uniform nomenclature there appears to be no serious quarrel The question has been raised, however, of whether a proper choice can be made at this time, and several correspondents find it particularly repugnant that a decision should be made by a four-member subcommittee that is not representative of the full spectrum of opinion in the field The tentative report did not attempt to document its position on points 2 and 3 of the outline of the argument presented above, though references were cited, and the correspondence accordingly did not provide a basis for debate on these issues There were, however, several expressions of doubt that the facts presently available compel a decision in favor of the principles, either serologic or genetic, upon which the Rh-Hr nomenclature is based Furthermore, in several instances, opinion was expressed to the effect that correctness in principle is not a proper issue in this matter, either of the available systems of nomenclature may be used to represent a test situation regardless of the genetic and serologic bases conceived for the situation In fact, it was pointed out that the present inclination to consider the C-D-E-F symbols as reflecting "completely linked genes' is operationally indistinguishable, on genetic grounds, from the Rh-Hr postulate of multiple allelism Differences on the serologic level were not discussed, but it was asserted that many immunologists do not recognize distinctions among agglutinogens, blood factors, and genes

To understand and use this chart quickly and easily the phenotype names and numbers should be used in conjunction with the table of Rh Hr reactions (table 3) 1 Determine the phenotypes of the blood of the mother putative father and the child or children using potent and specific anti Rh_0, anti rh, anti rh and anti hr′ serums including appropriate controls 2 Assign the corresponding phenotype symbol and number to each individual tested 3 Find the assigned number of the mother and father on the side and top columns of the table and locate the box at which both intersect 4 The child or children are not possible from this mating if their assigned numbers appear in this box 5 Phenotype numbers given in boldface represent children for whom maternity

The most forcefully expressed contrary opinion, however had to do with the question of usage and convenience Several correspondents, particularly from Britain and Europe, asserted that the C-D-E-F system or some modification of it is in exclusive use there and attested to its clarity and adequacy In America too, this system appears to have been adopted by teachers in at least two medical schools and a state of confusion is anticipated if in medical reporting a "return" to the Rh-Hr nomenclature, which is unfamiliar to the graduates of these schools, is advocated The grounds for adopting the C-D-E-F rather than the Rh-Hr system in teaching are frankly expedient ones, it was repeatedly asserted that students do not comprehend test situations or communicate in terms of symbols involving primes, subscripts, bold-face, Roman, italic, and German script Correspondents who testified to the difficulty of teaching or communicating in such terms included several who believe that the Rh-Hr conceptual basis of multiple allelic control of related antigens might be more sound than the one gene–one antigen–one antibody–one symbol" basis of the C-D-E-F system

Finally, other correspondents expressed the hope that a new system of nomenclature might appear that would command a clear majority of scientific support and usage No strong opinions were expressed as to what this nomenclature should be like, although there were a few tentative suggestions In the interval, however, it was urged that the adoption of a uniform nomenclature should await decision by a more representative body than the present committee, after more extensive and intensive consideration than has yet been given this difficult subject

is excluded This table was prepared after an examination of a similar table prepared by Dr W C Boyd The phenotypes have been presented and numbered in *an order different from* that used by Dr Boyd The committee believes *this order to be more logical but Dr Boyd informs us that he still prefers* the order used in his version of the table He also informs us that he does not approve of the inclusion in the table of numbers corresponding to phenotypes of children who could not be born to the mother in question

Use of Newer Blood Factors in Cases of Disputed Parentage

Studies on the distribution and heredity of the agglutinogens and blood factors have shown that certain of them are related to others so as to form systems Certain blood factors have the peculiarity that blood lacking the factor or blood possessing the factor is extremely rare Table 5 summarizes the present status of knowledge of the human blood groups, with special reference to their medicolegal application When blood tests are carried out in problems of disputed parentage, the examination is usually limited to the A-B-O, M-N, and Rh-Hr systems Moreover, the tests are further limited to particular factors of these three systems In the preceding report of 1952, it was recommended that the medicolegal application of the blood test should not be extended further for the time being For reasons pointed out below, it is still premature to apply these newer tests routinely in medicolegal cases, though there might be special circumstances when their use would be permissible

A-B-O System—For general medicolegal purposes, the blood tests should be restricted to the factors A and B and to the four blood groups, O, A, B, and AB The tests should include examination of the serum (or plasma) of each individual for its isoagglutinin content, as well as tests on the red blood cells with anti-A and anti-B serums[6] Some workers recommend the use of high-titered group O testing serum in order to detect blood cells of the rare subgroup A_4 Tests for the subgroups of A are not sufficiently reliable for medicolegal use The serologic distinction between agglutinogens A_1 and A_2 is not sharp, so that the diagnosis is not infrequently difficult to make, especially in newborn babies and in individuals of group AB Moreover, intermediate forms exist between A_1 and A_2 Therefore, this committee finds that tests for the subgroups of A remain too unreliable for general medicolegal use At any rate, the chances of excluding paternity for a falsely accused man, which is about 18 5% using factors A and B, would be increased by only 1 or 2% were the subgroups of A applied (table 5)

M-N-S System—For medicolegal purposes the paternity blood tests are preferably restricted to the factors M and N Antiserums for these factors are prepared in rabbits, and from most of the antiserums satisfactory reagents can be prepared that give reactions of high avidity and specificity The reagents, particularly for factor N, are generally of low titer, but this does not appear to interfere with the reliability of the results It is recommended that the tests be carried out with at least two different antiserums of each specificity Satisfactory anti-N reagents can also be prepared from the seeds of Vicia graminae, which may be used if desired for purposes of confirmation[illegible] Under no circumstances should the diagnosis be based solely on tests with such extracts Tests on tens of thousands of families and mother-child combinations have proved that exclusion of paternity based on the M-N types is as reliable as exclusion based on the A-B-O tests

Reagents for factor S are obtained from human individuals sensitized by transfusion or pregnancy While the titer of these reagents is generally low, the reactions are of high avidity and specificity like the tests for M and N However, the number of studies to date on the S factor is small, because of the scarcity of this reagent, which, unlike anti-M and anti-N cannot, at present, be produced at will Therefore, the medicolegal application of the S test should be limited to selected cases, and exclusions of parentage based on this test alone should be qualified by pointing out that the statistical basis for this test is still incomplete, though there is no reason to doubt its validity Reagents for anti-s are even rarer than anti-S Moreover, the anti-s reagents available up to the present had to be used with the antiglobulin technique, and the results were reproducible only with difficulty For these reasons, the medicolegal application of factor s is not recommended for the present It is hoped that the technique of the test for factor s will be perfected, since the combined tests for S and s will increase substantially the chances of excluding paternity The addition of anti-S alone adds about 40% as much as the addition of both anti S and anti-s Antiserums for factors Hunter and Henshaw (table 5) are still in limited use, so that such tests are not yet available for medicolegal purposes Recent work indicates that factor U is related to the M-N-S system, but, because of the almost universal distribution of this factor, it has little medicolegal importance

TABLE 5 —*Blood Groups in Man Medicolegal Application*

System	Blood Factors	Number of Identifiable Types	Isoantibodies		Identification*		Exclusion of Paternity

Factors with almost universal distribution	Vel and I	Negatively reacting bloods are very rare	None reported	1 case anti I 2 cases anti Vel				

* The figures for the chances given in this column are based on figures given in Race and Sanger s Blood Groups in Man ed 2 1954 Additional relevant calculations have been made by Boyd *Boston Med Quart* I 28-29 1956

† Chances of success (1) Identification refers to the chance of proving that a given blood sample did not come from a specific individual because of a difference in blood group (2) Exclusion of paternity gives the chance of proving that a falsely accused man is not the father of a given child

‡ The combined chance of excluding paternity using the A B O M N and Rh Hr systems is approximately 55% The P, K k, Fy^a Jk^a and Lu^a factors if applied would increase the chances by only 6 or 7%

§ Some workers use the simpler symbols F and f for the blood factors of the Duffy system and the symbols J and j for the blood factors of the Kidd system

¶ The Diego factor is common however among Amerindians Recent work indicates that the rare blood factors Mi and Vw are related and belong to the M N S blood group system

Rh-Hr System —As has already been pointed out, in medicolegal cases the paternity blood tests are generally limited to the factors Rh_0, rh', rh″, and hr' Actually many more Rh-Hr factors have been found Of all the Rh-Hr factors known, the most important are the four Rh factors Rh_0, rh', rh″, and rh^w and the three Hr factors hr', hr″, and hr The reactions of these seven antiserums and the types they determine are given in table 1

As can be seen from table 1, as many as 28 sharply defined Rh-Hr phenotypes can be differentiated with the aid of the 7 Rh-Hr serums, corresponding to which there are 55 genotypes theoretically possible This does not take into account the additional phenotypes and genotypes resulting from the existence of Rh_0 variants and certain other rare Rh-Hr agglutinogens In practice the number of phenotypes encountered will be considerably smaller, because many of the phenotypes are rare Thus, if only those phenotypes that have an incidence of 1% or higher are counted, there are only 9 or 10 phenotypes among those theoretically possible that are apt to be encountered in tests on a short series of individuals The medicolegal expert must also be aware of the existence of rare individuals with an agglutinogen having the factor Rh_0 but lacking both factors of each of the two pairs rh'-hr' and rh"-hr" Such bloods have been labeled as "deletions," but a more conservative designation for this type is Rh_0^x with $R^{0x}R^{0x}$ as the corresponding genotype The existence of these rare agglutinogens affects the validity of the rule that an rh'-negative parent cannot have an hr'-negative child and an hr'-negative parent cannot have an rh'-negative child For example, if the putative father belongs to type Rh_1Rh_1 and the child to type Rh_2, paternity is not necessarily excluded, provided the man's genotype is R^1R^{0x}, and the baby's genotype R^2R^{0x} Therefore, such exclusions of paternity call for some mild qualification No qualification is needed when the rule is recorded as follows An rh'-negative parent lacking the Rh_0 factor cannot have an hr'-negative child, and an hr'-negative parent cannot have an rh'-negative child lacking the Rh_0 factor It has been found that individuals who carry the gene R^{0x}, either heterozygous or homozygous, have red blood cells which are clumped by conglutinating Rh_0 antiserums, even when the tests are carried out in saline medium It would appear, therefore, that this additional test would eliminate the need for any qualification

The availability of anti-rh^w serum further increases the chances of excluding paternity Aside from the fact that the rh^w factor cannot appear in a child unless present in one or both parents, particular combinations exclude paternity in certain instances where no decision would be possible without the aid of this antiserum For example, a parent of type Rh_1^wrh cannot have a child of type Rh_1Rh_1, and a parent of type Rh_1Rh_1 cannot have a child of type Rh_1^wrh

The use of anti-hr serum (table 1) may help resolve certain problems of disputed parentage The recently discovered factor hr has no Rh factor counterpart, thus differing from factors hr' and hr", which have the counterparts rh' and rh" respectively With possible rare exceptions, the factor hr has been found present only in the agglutinogens determined by genes r and R^0 and is absent from the agglutinogens determined by the genes r', r'', r^y, R^1, R^2, and R^z Thus, the counterpart of anti-hr, which may be designated anti-rh, when and if it is found, can be recognized by the fact that it will behave like a mixture of anti-rh' and anti-rh" When a putative parent belongs to type Rh_z (blood with the three factors Rh_0, rh', and rh"), and the child to type rh or Rh_0, or vice versa, parentage is excluded, provided it can be shown that the individual of type Rh_z is not carrying the genes R^z or r^y This may be possible with the aid of anti-hr serum, namely, if it can be shown that the blood has factors hr' and hr" but lacks the hr factor (table 1)

As already mentioned, certain workers routinely use anti-hr" serum in medicolegal cases of disputed paternity The use of this serum adds little to the chance of excluding paternity because of the low frequency of hr"-negative individuals in the population (table 1) Moreover, the experimental basis for the practical application of these tests is not very firm, since only a few publications describe heredity studies in which anti-hr" serum was used Therefore, the Committee does not recommend the routine medicolegal application of this reagent, though it is recognized that the test may prove helpful in occasional selected cases

Recent work has revealed the existence of still other factors belonging to the Rh-Hr system, notably, factor V, often found associated with the genes r and R^0, especially in Negroes [8] In addition, a series of new Rh factors has been discovered that, with rare exceptions, occur in association with the factor Rh_0 (similar to the association of factor rh^w with rh') and that have tentatively been designated as Rh^A, Rh^B, and so forth [9] Obviously, the medicolegal application of such factors is premature Indeed, because of the lack of availability of adequate amounts of suitable antiserums and the limited knowledge due to the small number of investigations carried out to date, the routine use in medicolegal work of factors rh^w, hr", and hr is inadvisable This Committee recommends, therefore, that for routine medicolegal work, for the present, the Rh-Hr tests be limited to the factors Rh_0, rh', rh", and hr'

P System —The antiserums available for use have been mostly of human origin and contain irregular agglutinins giving most distinct reactions at low temperature Due to the presence in such serums of interfering nonspecific cold agglutinins, and the low titer of these reagents, the results of such tests are not sufficiently reliable for medicolegal purposes This committeee, therefore, recommends that the P tests should not be used in routine medicolegal practice Recent work indicates that the high incidence factor Tj^a is related to the P system It should also be mentioned that the so-called Q factor of Japanese investigators is probably identical with factor P [10]

Lewis System —Knowledge of the Lewis system, insofar as its medicolegal applications are concerned, is still in a confused state due to the lack of potent and specific reagents The only reagents available appear to be natural irregular isoagglutinins encountered in rare human serums, which react best at low temperature and rarely have a titer exceeding 2 to 4 units Due to the presence of interfering cold agglutinins, especially anti-O in many anti-Le^b serums, these tests are not sufficiently reliable for medicolegal use

Kell System —Many additional examples of anti-K serum have been encountered during recent years, and all have similar properties, in that they react best by the conglutination and antiglobulin technique Therefore, these reagents should not be used for typing blood with red blood cells already coated by antibody globulin, as in infants with hemolytic disease or patients with acquired hemolytic anemia Moreover, the agglutinates are somewhat more fragile than in Rh-Hr reactions, so that the reactions are not always readily reproducible This difficulty in technique has apparently discouraged extensive investigation of this system Furthermore, the use of the rare anti-k serum adds little information, since only one out of approximately 500 bloods fails to clump in such antiserums For these reasons, as well as the small number of family studies carried out to date, this committee recommends that the K-k tests should not be used in routine medicolegal practice but be reserved for special cases only

Duffy and Kidd Systems—The Duffy and Kidd systems are grouped together because of the similarity in behavior of the available reagents These reagents give the most distinct reactions only by the antiglobulin method, and the agglutinates are even more fragile than those encountered in the Kell tests Because of the difficulty in reproducing the reactions, and the small number of family studies carried out to date, in the opinion of this committee, the Duffy and Kidd tests are not suitable for routine medicolegal purposes Therefore, this committee recommends that tests for factors F (or Fy^a) and J (or Jk^a) should not be carried out in routine medicolegal practice However, there are some experts who feel that these tests are sufficiently reliable for medicolegal use

The so called family or private factors (table 5) have little or no value in medicolegal practice because of their rarity in the general population

Blood Tests as Circumstantial Evidence of Parentage

The expert in the field of blood grouping is accustomed to think of blood tests as a method of establishing nonparentage only When the blood types of the child match genetically with those of the supposed parents this is considered an inconclusive finding because of the possibility of coincidence However, with the increase in the number of detectable blood factors and the number of blood group systems whose mode of inheritance is known, the possibility suggests itself of using blood tests as circumstantial evidence of paternity or maternity Assignment of parents is occasionally possible in disputed parentage cases involving cattle [11]

In almost all cases, despite the combined use of A-B-O, M-N, and Rh-Hr tests, such circumstantial evidence of parentage will be weak For example, if both putative parents and the child belong to type O M Rh_1rh, there is a substantial chance of coincidence Exactly where to draw the line is difficult to state This committee feels, therefore, that the use of blood tests as circumstantial evidence of paternity is not advisable in routine medicolegal practice In fact, attempts to apply blood tests in this way carry the danger that they may serve to confuse the issue and cause the court to discredit the blood tests altogether

On the other hand, there are certain unusual cases that cannot be ignored, where the use of blood tests as circumstantial evidence of paternity or maternity appears to be justified For example, if the putative father belongs to type rh″, the mother to type rh, and the child to type rh″, the conscientious examiner will feel obligated to call this unusual circumstance to the attention of the court Since rh″ occurs in less than 0 5% of the population, the coincidental presence of this type in the child and the accused man is circumstantial evidence of paternity, assuming, of course, it is ascertained that a co-relative such as a brother of the same type as the accused cannot be involved However, this committee feels that such an observation should not be included in the official report but should be mentioned and explained in a covering letter accompanying the report Other situations in which the results of blood tests may perhaps be considered circumstantial evidence of paternity are cases where the child and accused man both belong to type rh′ or both have the factor rh^w, lacking from the blood of the mother As another example the instance where the baby and the putative father both are Kell positive and group B, while the mother is Kell negative and group O, may be cited

Model Blood Grouping Law

To further the medicolegal application of blood grouping tests in cases of disputed paternity, the passage of state laws authorizing courts to order these tests appears to be necessary At the time when the previous report of this committee was published, laws had been passed in the states of Maine, Maryland, New Jersey, New York, North Carolina, Ohio, Pennsylvania, South Dakota, and Wisconsin During the past five years four more states have been added to the list, namely, Connecticut, Massachusetts, Minnesota, and New Hampshire The main obstacle to the adoption of similar laws by all states is the dearth of qualified experts specializing in the field of blood grouping Even among workers in the field, unnecessary controversy regarding nomenclature certainly has not helped to instill confidence in the tests among lawyers and jurists From the point of view of the legislator and jurist, the wider medicolegal application of blood tests may be fostered by the availability of a model blood-test law A Uniform Act on Blood Tests to Determine Paternity was drafted by the National Conference of Commissioners on Uniform State Laws and approved by the conference at its annual meeting in San Francisco, Sept 8-13, 1952 This act was later approved by the American Bar Association at its meeting in San Francisco, Sept 19, 1952

The proposed uniform act has many commendable features However, the following simplified version of the proposed act would be an improvement, in the opinion of this committee

Uniform Act on Blood Tests in Cases of Disputed Parentage in Man

Be it enacted (use the proper enacting clause for the state)

Section 1 Authority for Test In a civil action in which parentage is a relevant fact, the court upon its own initiative or upon motion of any party in the action shall order the mother, child, and alleged father to submit to blood tests

Section 2 Selection of Experts The tests shall be made by qualified experts in the field of blood grouping who shall be appointed by the court For a list of such experts the court shall apply to the local medical association or to the American Medical Association The expert may be called by the court to testify on the findings and shall be subject to cross-examination Any party may demand that other qualified experts perform independent tests under order of the court

Section 3 Compensation of Expert Witnesses The compensation of each expert appointed by the court shall be fixed at a reasonable amount and paid as the court shall order

Section 4 Effect of Test Results If the blood tests show that the alleged parent is not the parent of the child, such a finding shall be admissible as evidence If the blood tests show the possibility of the alleged parents parentage the admission of such evidence shall be within the discretion of the court

Section 5 Effect on Presumption of Legitimacy The presumption of the legitimacy of a child born during wedlock is overcome if the court finds that the blood tests show that the husband is not the father of the child

Section 6 Applicability to Criminal Actions This act shall also be applicable in criminal cases in which the problem of parentage arises, such as cases of rape and kidnapping

Section 7 Severability Clause If any part of this act is declared invalid the remaining portion shall continue in full force and effect and shall be construed as being the entire act

SECTION 8 Short Title This act may be cited as the Uniform Act for Blood Tests in Disputed Parentage in Man -

SECTION 9 Repeal All acts or parts of acts which are inconsistent with the provisions of this act are hereby repealed

SECTION 10 Time of Taking Effect This act shall take effect

Two important aspects of the medicolegal application of blood tests are the questions of qualifications of experts and the application of blood tests in the examination of dried stains of blood and secretions These two subjects are not treated here because they have already been discussed in the report published in 1952, and no important changes have occurred It is essential that only qualified workers carry out these examinations, because serious errors have occurred when inexperienced workers undertook to perform these tests It must be borne in mind that blood tests are performed by natural persons, so that experts to be qualified are individuals and not institutions A detailed discussion of the pitfalls in the grouping of dried blood stains can be found in a recent article on the subject [12] The question of qualifications of experts remains a difficult and unsolved problem requiring serious study

Summary and Conclusions

Because the use of two systems of nomenclature for the Rh-Hr system leads to confusion and misunderstanding, the Committee on Medicolegal Problems of the American Medical Association recommends the adoption of a single uniform system for medicolegal reports Of the two available systems, the Committee favors the Rh-Hr over the C-D-E for what it considers strong reasons It recognized faults in both systems, and suggests that the achievement of an internationally acceptable terminology is a desirable objective In the interim, it is recommended that, unless and until some other convention can be agreed upon, the original Rh-Hr notations be kept as the standard and sole nomenclature for preparing approved medicolegal reports on Rh-Hr types

It is recommended that routine medicolegal applications of blood grouping be restricted at present to tests for the four blood groups O, A, B, and AB of the A-B-O system, the three types M, N, and MN of the M-N-S system, and factors Rh_0, rh′, rh″, and hr′ of the Rh-Hr system Tests for additional factors and systems are considered insufficiently established for routine use at present, although they may provide evidence in particular selected cases Such evidence should be submitted in a separate letter not part of the standard report and should be presented with proper caution Similarly, the value of rare combinations of groups providing indication of paternity, in contrast to the conventional use of the tests to establish only nonpaternity, should be recognized in unusual cases but should be treated with caution in a separate communication not part of the definitive report The question of qualification of experts remains a difficult and unsolved problem requiring serious study

Recent Court Decisions

Prochnow v *Prochnow*, 80 N W (2d) 278 (Wis, 1957) —The results of a blood test excluding paternity were held not to be conclusive where the statute requires that "any party asserting the illegitimacy of the child shall have the burden of proving beyond all reasonable doubt that the husband was not the father of the child" The child was held to be legitimate on testimony of wife that she had timely intercourse with her husband and none other

Ross v *Marx*, 93 A (2d) 597 (N J, 1952) —Medical testimony was introduced to show the results of blood-grouping tests conducted on the plaintiff, her child, and the defendant The tests definitely established nonpaternity The trial judge stated that he thought the results of such tests were conclusive on the issue of paternity The superior court acknowledged that, under statute, the results of such tests are admissible in evidence only when they definitely establish exclusion It held, however, that the results are not conclusive Evidence that the test was incompetently administered would be properly admissible

Clark v *Rysedorph*, 118, N Y S (2d) 103 (N Y, 1952) —During the course of the trial the judge ordered three separate blood-grouping tests to be conducted on the plaintiff, her child, and the defendant Two M-N tests and one A-B test were given Each test excluded the defendant as the father of the plaintiff's child When such evidence is uncontradicted, it is conclusive To reject such testimony, said the court, would be to ignore scientific facts

Miller v *Domanski,* 97 A (2d) 641 (N J, 1953) – The trial court, pursuant to state statute, directed Dr Philip Levine to perform blood-grouping tests on the plaintiff, her child, and the defendant in a bastardy proceeding Dr Levine testified that, unless the assumption was made that the plaintiff had a very rare and unusual genetic make-up, the tests did show exclusion The court then refused to permit him to testify as to the results of the tests, even though, when the pertinent statute was enacted in 1939, the problem of an unusual serologic make-up was unknown to medical science The superior court held that the trial court correctly applied the statute, which forbids using the results of blood-grouping tests as evidence except where such tests definitely establish exclusion, and judgment for the plaintiff was therefore affirmed

United States ex rel Lee Kum Hoy v *Shaughnessy,* 115 F Supp 302 (S D N Y, 1953) –The admission into evidence at an administrative hearing of the bare blood-grouping reports and the failure to provide opportunity to cross-examine the doctor as to the qualifications of the test constituted a denial of due process

United States ex rel Dong Wing Ott v *Shaughnessy,* 116 F Supp 745 (S D N Y, 1953) –An administrative tribunal does not violate due process by taking official notice of scientific treatises on the subject of blood-grouping tests in exclusions of paternity

Chin Wing Gwong v *Dulles,* 139 F Supp 116 (D R I, 1956) –Blood tests excluding paternity were denied conclusive weight on the ground that the qualifications of the testing procedure were not shown

Pomainville v *Bicknell,* 109 A (2d) 342 (Vt, 1954) Conclusive weight to blood tests excluding paternity was denied by the court because the technician who conducted the tests failed to testify

People v *Nichols,* 67 N W (2d) 230 (Mich, 1954) The results of blood-grouping tests that do not exclude paternity have "not the slightest probative value or tendency to prove paternity and are inadmissible in evidence

Lee On v *Dulles,* 131 F Supp 310 (Mass, 1955) – The refusal to submit to a test by a nonparty whose blood groupings are relevant to the issue of paternity does not warrant an inference that the nonparty feared the results where the refusal is due to 'the inability to meet costs of blood tests and expert witnesses to controvert unfavorable conclusions which government experts might erroneously draw from the results of these tests"

Lee Wing Get v *Dulles,* 18 F R D 415 (E D N Y, 1955) –In an action for derivative citizenship, the court, apparently forgetting the demise of the Rules of Conformity Act, ordered the blood test of a nonparty mother under New York Civil Practice Act, section 306-a

Fong Sik Leung v *Dulles,* 226 Fed (2d) 74 (9 Cir, 1955), *Yee Szet Foo* v *Dulles,* 18 F R D 237 (S D N Y, 1955), *Dulles* v *Quan Yoke Fong,* 237 Fed (2d) 496 (9 Cir, 1956) –Where an infant seeks a declaratory judgment in a suit by his father-guardian *ad litem,* the court may not order, under rule 35 (a) of the Federal Rules of Civil Procedure, blood tests of the father-next friend, the parents, or the brothers or sisters

Chin Nee Deu v *Dulles,* 18 F R D 350 (S D N Y, 1955) –Under the provisions of rule 35 (a) of the Federal Rules of Civil Procedure, in an action to which the physical condition of a party is in controversy, the court may order him to submit to a physical examination by a physician Thus, where an infant seeks a declaratory judgment of his own derivative citizenship in an action brought by his 'father as next friend, the infant may be compelled to submit to a blood test, but the court may not order blood tests of the father-next friend

NOTE Blood tests for nonparentage on an individual seeking admission to this country on the basis of derivative citizenship, without testing his putative parents, would obviously be pointless

---

Arteriosclerotic Aneurysms –Arteriosclerotic aneurysms occur in degenerative disease of the thoracic aorta and are a malady of the elderly Arteriosclerotic aortic aneurysms may be asymptomatic, but often there is a history of hypertension When symptoms occur the situation is ominous Backache may be due to erosion of the bodies of the dorsal vertebrae by the aneurysm, hoarseness can be caused by recurrent laryngeal nerve paralysis, and hemoptysis can be caused by erosion or stenosis of a large pulmonary artery In a small series of six cases diagnosed with the aid of angiocardiography the majority had symptoms due to the aneurysm, of these, three (50%) were dead within a year Diagnosis of aneurysms of the thoracic aorta depends upon the roentgen findings of mediastinal or hilar masses or an enlarged aorta Differentiation from mediastinal tumors may be difficult, if not impossible It then becomes necessary to perform contrast studies of the cardiovascular system Angiocardiography can be depended upon to reveal saccular and fusiform aneurysms, as well as dilatation, tortuosity, unfolding and congenital anomalies of the aorta The diagnosis of arteriosclerotic aneurysms of the aorta depends upon the presence of a negative history and serologic test for syphilis in the older age groups, and the location of the aneurysm in the arch and descending portions The absence of severe dilatation and a regular smooth ascending aorta favor the diagnosis of arteriosclerosis The decision to perform surgery for arteriosclerotic thoracic aneurysms must take into account the advanced age and the tendency for arteriosclerosis to occur elsewhere In the heart, there may be coronary thrombosis or insufficiency, in the brain, cerebral thrombosis or hemiplegia, in the abdomen, aortic aneurysm or occlusion, and in the legs, arterial occlusion or insufficiency Despite all these, constant vigilance to detect the case suitable for surgery is recommended –I Steinberg, M D, Diagnosis of Arteriosclerotic Aneurysms of the Thoracic Aorta, *Annals of Internal Medicine,* February, 1957

COMMITTEE ON REHABILITATION

REPORT OF THE COMMITTEE ON REHABILITATION

The following report, which has been reviewed by the Board of Trustees of the American Medical Association, has been adopted for publication by the Association's Committee on Rehabilitation.

Ralph E. De Forest, M.D., *Secretary*

During the past 50 years medicine has made rapid advances in its ability to save the lives of the sick and injured. In this period our life span has been increased by more than one-third. A longer life span, together with a growing population and the increased number of persons injured during their daily activities of work and play, has resulted in a tremendous rise in the number of disabled individuals. The disabled and handicapped may become a burden on their families or society and may, even more unfortunately, become engulfed in their own feelings of insecurity, despair, and hopelessness. In response to the needs of the disabled and handicapped, a humanitarian movement, "rehabilitation," has developed and continues to expand in the United States. Since rehabilitation services are provided in so many ways, some confusion exists as to what is meant by and included within this term. However, some confusion is to be expected during the course of the expansion and development of almost any concept of such magnitude as that encompassed by present-day rehabilitation.

Stated in broad and simple terms rehabilitation services provide the total medical care needed to restore the sick and injured to maximal obtainable function, assist in psychological and social adjustment, provide occupational retraining if necessary, and either secure employment if possible, or at least strive to develop independence so that the individual may become self-sustaining. Success in rehabilitation is dependent, then, upon comprehensive care, including (1) medical and surgical diagnosis and treatment which must continue beyond the end of the 'acute stage' of disease or injury to the point of maximal reduction of physical or mental disability, (2) social service, (3) vocational retraining and counseling, and (4) job placement.

There is need for increased utilization of the many ancillary personnel such as physical therapists, occupational therapists, clinical psychologists, and others who work under direct medical supervision. The physician also needs to become aware of the great amount of work already done in the nonmedical aspects of rehabilitation in the fields of education, sociology, and vocational counseling and placement. This is necessary because, in addition to the medical care provided by the physician, the patient must also receive the benefits of these other fields dedicated to the betterment of the disabled. It seems reasonable to assume, however, that the physician should accept leadership in seeing that adequate and total rehabilitation services are available to his patients. The physician should take the lead and direct the rehabilitation team if the important, traditional physician-patient relationship is to be maintained and his patients are to receive all of the benefits total rehabilitation has to offer. To assure that ancillary personnel are adequately trained to assume their responsibilities as members of the rehabilitation team, physicians should also actively participate in teaching the medical aspects of educational programs for such personnel.

Every individual physician can and should assume responsibility for the rehabilitation of his patients. Accomplishment does not depend so much upon the rehabilitation center as it does upon the mobilization, integration, and provision of rehabilitation services. The physician should ascertain what rehabilitative, community, and specialized medical services are available, and direct his patient to them as necessary. Although both federal and private national organizations are interested in rehabilitation, actual service is provided to the individual at the local level. County and state medical societies should catalogue for the benefit of their members the various medical, social, and educational agencies providing services to the rehabilitee within the state, county, and community.

The Committee believes that its activities in the development of rehabilitation should proceed with the following objectives as guides to its work: (1) to coordinate the rehabilitation interests and activities within the councils, bureaus, committees, and departments of the American Medical Association, (2) to foster medical supervision of rehabilitation services and centers, (3) to study the problems and interrelationships of the medical, social, educational, and vocational aspects of rehabilitation, (4) to inform the medical profession of the availability of information regarding rehabilitation, (5) to collect information concerning the establishment of rehabilitation programs, their organization, methods of operation, and utilization by physician and patient, and (6) to encourage medical society interest and programs in rehabilitation.

In the process of carrying out this work, the Committee believes that some of the activities in which it might engage are as follows: (1) a review of the rehabilitation programs of national organizations through a perusal of written and published material and through conferences with representatives from these organizations, (2) a preparation of guides for medical societies to use in (*a*) reviewing the rehabilitation programs of local agencies and foundations, including availability of facilities and services and the extent and type of research, (*b*) determining the need for facilities and services, and (*c*) developing liaison with local groups concerned with rehabilitation, (3) the preparation of guides for sound rehabilitation services and facilities, and (4) publication of a series of articles in The Journal of the American Medical Association on all aspects of rehabilitation. Such articles would be prepared by persons well qualified in the various aspects of rehabilitation.

Members of the Committee on Rehabilitation are Frank H. Krusen, M.D., Chairman, H. B. Mulholland, M.D., Vice-chairman, Oscar A. Sander, M.D., Francis J. Gerty, M.D., and Guy A. Caldwell, M.D.

COUNCIL ON DRUGS

Formerly the Council on Pharmacy and Chemistry

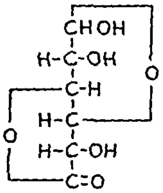
NEW AND NONOFFICIAL DRUGS

Formerly New and Nonofficial Remedies

Monographs and supplemental statements on drugs described here and in subsequent editions of New and Nonofficial Drugs are based on the evaluation of available scientific data and reports of investigations Applicable commercial names for preparations of evaluated drugs are listed at the end of monographs and parenthetically in the text of supplemental statements, additional commercial names of which the Council is informed will be included with subsequently published supplemental statements and annual editions of New and Nonofficial Drugs

H D Kautz, M D, *Secretary*

Glucurolactone—γ-Lactone of D-glucofuranuronic acid—The structural formula of glucurolactone may be represented as follows



Actions and Uses—Glucurolactone is the gamma lactone of glucuronic acid, an important body constituent that is believed to possess at least two significant metabolic functions It is an essential unit of tissue structure, comprising part of the composition of connective tissue and collagen, particularly of cartilage, periosteum, nerve sheath, joint capsule, tendon, and synovial fluid It also occurs in intercellular cement substance and in blood vessel walls Glucuronic acid is of additional metabolic importance as a detoxifying agent, combining with many foreign and deleterious substances that are then excreted in the urine as innocuous glucuronic acid conjugates

As a physiological body constituent, glucuronic acid and its more stable lactone have been considered possible therapeutic agents in several disease entities Although they were previously suggested for a variety of purposes, clinical experience has centered principally about the use of these compounds in the treatment of arthritis, rheumatism, and associated collagen diseases It has been surmised that the destruction of bone and cartilage, which characterizes these conditions, may result from a deficiency of glucuronic acid required for normal metabolism and that such deficiency may also involve the cement substance affected in the collagen diseases It has also been surmised that patients in this category may suffer from a defect in detoxicating mechanism as indicated by excessive toxicity from focal and other infections Although there is no valid evidence to support this view, glucurolactone has been proposed for use in arthritic conditions as an orally given absorbable, stable form of glucuronic acid to restore and maintain metabolic balance in fibrous tissue and to help meet daily detoxicating requirements Although some observers believe that the drug exerts a beneficial clinical effect, the number of patients in which such results have been reported is too small to permit any positive conclusion Since the presently available evidence is largely from uncontrolled studies, it is also difficult to determine whether the favorable responses thus far reported were due to the action of the drug or to spontaneous remissions so characteristic of this group of diseases Thus, while there may be some hypothetical reasons for the use of glucurolactone for the treatment of joint and collagen diseases, a definite statement regarding its usefulness must await the results of better controlled, long-term clinical studies

Unlike free glucuronic acid or its salts, glucurolactone is readily absorbed from the gastrointestinal tract It is apparently broken down to free glucuronic acid in the body, since detectable increases in this constituent may be found in the blood and urine after the oral administration of its lactone Both laboratory and clinical experience indicate glucurolactone to be a relatively nontoxic substance In humans, prolonged administration has not been accompanied by any manifestations of serious deleterious effects Occasionally, flushing of the face and mild gastrointestinal distress have been observed These effects usually subside with a reduction in dosage or with temporary withdrawal of the drug

Dosage—Glucurolactone is administered orally In the treatment of joint and arthritic-like conditions, the daily administration of 2 Gm of glucurolactone in four divided doses should be considered experimental If the drug is employed at all, administration for one month or more may be required before any therapeutic results are apparent Should a favorable effect be obtained, maintenance dosage and duration of subsequent therapy should be governed by individual response The trial of glucurolactone in arthritic patients does not obviate the need for more important and better established therapeutic measures

Applicable commercial name Glucurone

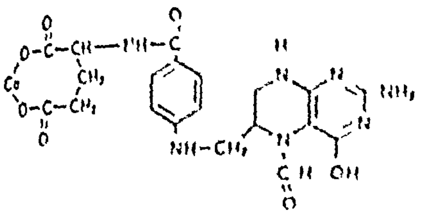
Leucovorin Calcium—Calcium 5-formyl-5,6,7,8-tetrahydropteroylglutamate.—The structural formula of leucovorin calcium may be represented as follows



Actions and Uses—Leucovorin calcium, the calcium salt of the active metabolite of folic acid, is utilized for growth of the bacterial species Leuconostoc citrovorum. Hence leucovorin is frequently referred to as citrovorum factor or, less commonly, folinic acid. In man and animals folic acid per se is metabolically inactive; it must be converted to leucovorin in the tissues in order to exert a stimulating effect on the proliferation of all blood cellular elements. If this conversion is blocked, as with the folic acid antagonists aminopterin or A-methopterin, hematopoiesis is depressed. This is, of course, the therapeutic effect desired in the treatment of acute leukemia of childhood. However, because of extreme potency and narrow margin of safety, therapy with the folic acid antagonists can be hazardous. Hematopoietic response is sometimes very difficult to control, and even small errors in dosage can lead to irreversible bone marrow depression. In such situations leucovorin calcium exerts a potent antidotal action, since it provides an exogenous source of the active hematopoietic principle, the biosynthesis of which is blocked. There is adequate laboratory and clinical evidence to show that prompt administration of the drug after overdosage with any of the folic acid antagonists results in a reversal of both hematopoietic toxicity and the generalized toxic effect on all reticuloendothelial tissue. Whenever possible, therapy with leucovorin calcium should be initiated before susceptible cell groups have become too damaged by folic acid antagonists to be responsive to antidotal action. Hence, in cases of inadvertent overdosage, leucovorin should be administered as soon as the error is detected; if a period of more than four hours intervenes, the drug may not be effective. Leucovorin calcium should not be administered simultaneously with folic acid antagonists in an attempt to modify or abort clinical toxicity. Such a regimen may nullify completely the desired therapeutic effect. If signs of toxicity appear after use of the folic acid antagonists, the offending drug should be withdrawn immediately, and, along with general supportive measures, leucovorin calcium should be administered on a daily basis until hematological and clinical improvement is noted.

Because leucovorin calcium supplies the active metabolite needed for the proliferation and maturation of blood cellular elements, it is effective in ameliorating the blood picture in the megaloblastic anemias associated with pregnancy, infancy, sprue, and nutritional deficiency. However, the ability of the blood-forming organs to convert folic acid to the citrovorum factor is not impaired in these anemias. Accordingly, in the megaloblastic anemias, no particular purpose is accomplished by using leucovorin calcium, which must be injected parenterally, instead of folic acid, which may be taken orally.

Before the introduction of cyanocobalamin (vitamin B_{12}), leucovorin calcium was used for the treatment of pernicious anemia. The action of the drug in this condition is essentially the same as that of folic acid. Thus, while leucovorin calcium may restore to normal the blood picture in patients with pernicious anemia, it is ineffective in the control of neurological symptoms. Cyanocobalamin, which overcomes both the hematological and neurological effects of pernicious anemia, has displaced both folic acid and leucovorin calcium in the treatment of this condition.

In therapeutic doses, leucovorin calcium appears to be essentially nontoxic. To date, no untoward effects or adverse reactions referable to the drug have been reported.

Dosage—Leucovorin calcium is administered intramuscularly. To counteract the toxic effects of folic acid antagonists the usual dose is 3 to 6 mg. per day. This is continued as long as signs of toxicity persist. For the treatment of megaloblastic anemias, a dose of 10 mg. may be injected daily for 10 to 15 days. Subsequent therapy and dosage is dependent upon the hematological response as reflected by both peripheral blood cell counts and bone marrow aspirations. Dosage of leucovorin calcium as an adjunct to cyanocobalamin therapy in the treatment of pernicious anemia has not been well defined, but amounts ranging from 0.2 to 15 mg. per day have been employed in this condition.

Applicable commercial name: Leucovorin.

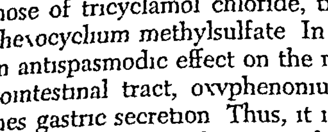
Oxyphenonium Bromide—Diethyl(2-hydroxyethyl)methylammonium bromide α-phenyl-α-cyclohexylglycolate.—The structural formula of oxyphenonium bromide may be represented as follows



Actions and Uses—Oxyphenonium bromide, a synthetic quaternary ammonium compound, is used clinically as an anticholinergic agent. Its pharmacological actions, side effects, and chemical structure are similar to those of tricyclamol chloride, tridihexethyl iodide, and hexocyclium methylsulfate. In addition to producing an antispasmodic effect on the musculature of the gastrointestinal tract, oxyphenonium bromide also diminishes gastric secretion. Thus, it is useful for the adjunctive management of peptic ulcer and for other disorders of the gastrointestinal tract, characterized by hypermotility or spasm, that are usually amenable to anticholinergic therapy. It may also be used in place of atropine or scopolamine as a p anesthetic medication in patients who are sens to the belladonna alkaloids. Currently availabl dence confirms the usefulness of oxyphenon

COUNCIL ON DRUGS

Formerly the Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL DRUGS

Formerly New and Nonofficial Remedies

Monographs and supplemental statements on drugs described here and in subsequent editions of New and Nonofficial Drugs are based on the evaluation of available scientific data and reports of investigations Applicable commercial names for preparations of evaluated drugs are listed at the end of monographs and parenthetically in the text of supplemental statements, additional commercial names of which the Council is informed will be included with subsequently published supplemental statements and annual editions of New and Nonofficial Drugs

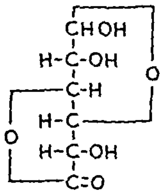
Glucurolactone —γ-Lactone of D-glucofuranuronic acid —The structural formula of glucurolactone may be represented as follows



Actions and Uses —Glucurolactone is the gamma lactone of glucuronic acid, an important body constituent that is believed to possess at least two significant metabolic functions It is an essential unit of tissue structure, comprising part of the composition of connective tissue and collagen, particularly of cartilage, periosteum, nerve sheath, joint capsule, tendon, and synovial fluid It also occurs in intercellular cement substance and in blood vessel walls Glucuronic acid is of additional metabolic importance as a detoxifying agent, combining with many foreign and deleterious substances that are then excreted in the urine as innocuous glucuronic acid conjugates

As a physiological body constituent, glucuronic acid and its more stable lactone have been considered possible therapeutic agents in several disease entities Although they were previously suggested for a variety of purposes, clinical experience has centered principally about the use of these compounds in the treatment of arthritis, rheumatism, and associated collagen diseases It has been surmised that the destruction of bone and cartilage, which characterizes these conditions, may result from a deficiency of glucuronic acid required for normal metabolism and that such deficiency may also involve the cement substance affected in the collagen diseases It has also been surmised that patients in this category may suffer from a defect in detoxicating mechanism as indicated by excessive toxicity from focal and other infections Although there is no valid evidence to support this view, glucurolactone has been proposed for use in arthritic conditions as an orally given absorbable, stable form of glucuronic acid to restore and maintain metabolic balance in fibrous tissue and to help meet daily detoxicating requirements Although some observers believe that the drug exerts a beneficial clinical effect, the number of patients in which such results have been reported is too small to permit any positive conclusion Since the presently available evidence is largely from uncontrolled studies, it is also difficult to determine whether the favorable responses thus far reported were due to the action of the drug or to spontaneous remissions so characteristic of this group of diseases Thus, while there may be some hypothetical reasons for the use of glucurolactone for the treatment of joint and collagen diseases, a definite statement regarding its usefulness must await the results of better controlled, long-term clinical studies

Unlike free glucuronic acid or its salts, glucurolactone is readily absorbed from the gastrointestinal tract It is apparently broken down to free glucuronic acid in the body, since detectable increases in this constituent may be found in the blood and urine after the oral administration of its lactone Both laboratory and clinical experience indicate glucurolactone to be a relatively nontoxic substance In humans, prolonged administration has not been accompanied by any manifestations of serious deleterious effects Occasionally, flushing of the face and mild gastrointestinal distress have been observed These effects usually subside with a reduction in dosage or with temporary withdrawal of the drug

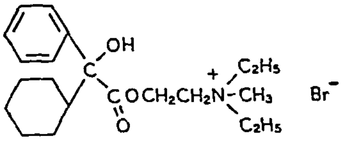
Oxyphenonium Bromide —Diethyl(2-hydroxyethyl) methylammonium bromide α-phenyl-α-cyclohexylglycolate —The structural formula of oxyphenonium bromide may be represented as follows



Actions and Uses —Oxyphenonium bromide, a synthetic quaternary ammonium compound, is used clinically as an anticholinergic agent Its pharmacological actions, side-effects, and chemical structure are similar to those of tricyclamol chloride, tridihexethyl iodide, and hexocyclium methylsulfate In addition to producing an antispasmodic effect on the musculature of the gastrointestinal tract, oxyphenonium bromide also diminishes gastric secretion Thus, it is useful for the adjunctive management of peptic ulcer and for other disorders of the gastrointestinal tract, characterized by hypermotility or spasm, that are usually amenable to anticholinergic therapy It may also be used in place of atropine or scopolamine as a preanesthetic medication in patients who are sensitive to the belladonna alkaloids Currently available evidence confirms the usefulness of oxyphenonium bromide as a potent antispasmodic but does not indicate any advantages that would distinguish the drug from other agents in this category

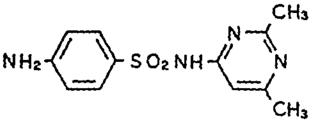
Side-effects to oxyphenonium bromide include those of the anticholinergic agents in general Blurring of vision, dryness of the mouth, difficulty in urination, and constipation may follow its clinical use Less common reactions have included weakness, dizziness, drowsiness, nausea, vomiting, headache, and tachycardia The drug is contraindicated in the presence of glaucoma, prostatic hypertrophy, and pyloric obstruction

Dosage —Oxyphenonium bromide is given orally, subcutaneously, or intramuscularly When immediate action is desired in severe gastrointestinal spasm with pain, 1 to 2 mg (0 5 to 1 cc of a 0 2% solution) may be injected subcutaneously or intramuscularly every six hours, oral therapy should then be substituted as soon as possible The usual oral dosage for adults is 10 mg four times daily Dosage should be adjusted, however, according to individual response and the appearance of side-effects For children, dosage is reduced proportionally according to age

Applicable commercial name Antrenyl Bromide

Ciba Pharmaceutical Products Inc cooperated by furnishing scientific data to aid in the evaluation of oxyphenonium bromide

Sulfisomidine —N′-(2,6-Dimethyl-4-pyrimidinyl)sulfanilamide —The structural formula of sulfisomidine may be represented as follows



Actions and Uses —Sulfisomidine, a structural isomer of sulfamethazine, is useful for the treatment of systemic and urinary tract infections caused by microorganisms that are susceptible to the bacteriostatic effects of sulfonamides In contrast to most other agents in this class, sulfisomidine is not readily acetylated in the body Thus, after oral administration, only about 5 to 10% of total blood sulfonamide is conjugated, and about 90% of the drug appears in the urine in the free form Since the free form of the drug is soluble in acid urine, sulfisomidine compares favorably with the other sulfonamides with respect to renal toxicity Hematuria and crystalluria are only rarely encountered Hence, concomitant alkalinization of the urine is not necessary to increase the solubility of the drug As with all sulfonamide therapy, however, fluid intake should be maintained above 1 5 liters daily Aside from diminished renal toxicity, the side-effects of sulfisomidine are similar to those of other sulfonamides (See the general statement on sulfonamides and on pyrimidine derivatives in New and Nonofficial Remedies)

Dosage —Sulfisomidine is administered orally The initial dose in severe infections is calculated on the basis of 0 1 Gm per kilogram of body weight Subsequent doses of one-sixth the initial dose should be given every four hours (six times a day) until the infection is well under control Then dosage is decreased to four times a day until a cure is effected

Applicable commercial name Elkosin

Ciba Pharmaceutical Products Inc cooperated by furnishing scientific data to aid in the evaluation of sulfisomidine

COUNCIL ON FOODS AND NUTRITION

Report to the Council

The Council has authorized publication of the following condensation of a report on atherosclerosis and diet which appears in the August, 1957, issue of Circulation *The report was prepared by the nutrition committee of the American Heart Association in cooperation with the Society for the Study of Arteriosclerosis*

Philip L White, Sc D , *Secretary*

ATHEROSCLEROSIS AND THE FAT CONTENT OF THE DIET

I H Page, M D , Cleveland, F J Stare, M D , Boston, A C Corcoran, M D , Cleveland, H Pollack, M D
and
C F Wilkinson Jr , M D , New York

Atherosclerosis in all probability has no single cause Among those factors presently implicated are (1) heredity, (2) diet, (3) anatomy of the blood vessel wall, (4) arterial blood pressure, (5) lipid content of the blood, and (6) sex Because atherosclerosis is a focal lesion, its consequences are widely variable There is no practical means of clinical diagnosis of uncomplicated, potentially reversible lesions The approach to this problem by animal experiments has shown that atherosclerosis which is closely similar to, but not necessarily identical with, the human type can be produced in a variety of experimental animals by dietary variations The results of such experiments have had a significant influence on the opinions of many clinicians

The clinical diagnosis of coronary arterial heart disease dates substantially from the first decade of this century No one questions the remarkable increase in the reported number of cases of this condition Undoubtedly the wide use of the electrocardiogram

---

From the Division of Research, Cleveland Clinic (Drs Page and Corcoran), the Department of Nutrition, Harvard School of Public Health (Dr Stare), and the New York University Post-Graduate School of Medicine (Drs Pollack and Wilkinson)

in confirming clinical diagnosis and the inclusion, in 1949, of arteriosclerotic heart disease in the International List of Causes of Death play a role in what is often believed to be an actual increased prevalence of this disease

The incidence of coronary heart disease has been reported to be associated with certain dietary habits, for instance, with the intake of fat Comparative nutritional surveys range from estimates based on the food balance sheets of two nations to carefully measured food intakes of individuals Estimates of national food balances may indicate trends in single countries or demonstrate wide differences in the adequacy of the diets available, but they have little application to small groups or to small differences

That the genetic factor may be an influence is indicated by a recent cooperative study made by the life insurance companies For periods of up to 15 years, they investigated 18,000 insured lives and showed conclusively that persons who had reported two or more cases of early cardiovascular renal disease in their families were subject to death rates from cardiovascular disease that were one and three-fourths to two and one half times greater than prevailing rates among all persons insured at standard premium rates [1]

Clinical Approach

The clinical approach to relating lipids to atherosclerosis depends primarily upon the association of increased incidence of atherosclerosis and coronary arterial disease with certain other diseases such as diabetes, myxedema, nephrosis, and xanthromatosis, all of which are commonly associated with hyperlipemia and hypercholesteremia Experience indicates that the equation of atherosclerosis with hypercholesteremia is presumably valid, but it does not establish the association between fat intake and hypercholesteremia

Cholesterol

Many years ago the clinical association between hypercholesteremia and atherosclerosis was correlated with the finding that rabbits fed cholesterol in oil developed atherosclerosis Cholesterol, once regarded as an unmetabolizable building block in animal tissues, became to many the villain underlying arterial catastrophe Although biologically the least significant, a large factor in this association was that the Liebermann-Burchard reaction made measurement of serum cholesterol easier than measurement of other serum lipids In fact, the reaction may have concentrated too much attention on cholesterol at the expense of substances of equal or greater potential interest The concentrations of plasma lipids usually tend to vary simultaneously in the same direction, and any one of them might be as significant as cholesterol

Fat

Total Fat Intake—Perhaps the total consumption of fat is relevant to clinical atherogenesis Keys,[2] in particular, has placed emphasis on the proportion of total dietary calories contributed by the common food fats Certainly there is an abundance of data, both clinical and experimental, which tend to relate excess fat intake to atherosclerosis Unfortunately, other significant parameters such as total caloric intake, relative rate of caloric expenditure, true obesity, and exercise are not easily disentangled from the problems of excess fat intake Consequently, this hypothesis finds opposition in some quarters

Animal vs Vegetable Fat—The possibility has been raised that the kind rather than the amount of fat in the diet is responsible for atherogenesis The first area of study has been a comparison of effects of animal fats with those of vegetable fats

Some of the relevant data comes from studies of vegetarians In one study it was found that serum cholesterol levels were higher in nonvegetarians than in lacto ovo-vegetarians and true vegetarians The lowest concentrations of cholesterol were found in the true vegetarians, in spite of the fact that 35% of their total calories came from fat

The possible association between vegetarian diets and low levels of serum cholesterol is tested by the data from a study of Eskimos,[3] who have a high intake of meat and fat With a procedure that yielded a mean value of 177 mg per 100 cc of total serum cholesterol for a control group of Canadians, the mean in 27 Eskimos was found to be 141 mg (range 93 to 222) and in 6 Devon Island Eskimos 132 mg (range 116 to 158) The fats consumed were largely of marine origin and, like vegetable fat, relatively unsaturated However, tuberculosis is common among Eskimos and may account for the relative lipopenia

Unsaturated Fats—The reported effects of vegetable fats on the cholesterol content of blood may be a function of their degree of unsaturation and/or of their content of so-called essential fatty acids The parameter of saturation of fat as a significant factor in cholesteremia, and by extension, in atherosclerosis, recently has been explored in humans by Kinsell,[4] Ahrens,[5] Beveridge,[6] and Bronte-Stewart [7] Their experiments showed that relatively unsaturated fats of vegetable or marine origin tend to lower serum cholesterol levels, whereas hydrogenated vegetable fats usually, and saturated animal fats rather regularly, tend to increase serum cholesterol levels

Speculative hypotheses, like those of Sinclair [8] and Schroeder,[9] have been formulated The starting point of this type of hypothesis is that cholesterol is normally esterified with unsaturated fatty acids When these are unavailable, cholesterol esterifies with saturated fatty acids provided by the dietary fats or synthesized in the body from carbohydrate The hypothesis states that it is these saturated cholesterol esters which tend to be deposited in the arterial intima Important to this concept would be the body's inability to form arachidonic acid from linoleic acid (the so-called essential fatty acids), this latter synthesis may depend on pyridoxine Therefore, pyridoxine deficiency might have the same effect as a deficiency of unsaturated fatty acid

The fact is that the basic problem is not lipemia, hypercholesteremia, or hepatic lipid excess, but it is atheromatosis and, in particular, myocardial infarction Atheromas have not been described or associated clinically or experimentally with fatty acid deficiency With the exception of Hartroft and Thomas' [10] recent production of myocardial infarction in animals on certain dietary regimens high in fat, myocardial infarction has not been precipitated in animals by excessive intake of any particular fat or of cholesterol or by a deficiency of pyridoxine or any unsaturated fatty acid

Fat and Clotting

The hypothetical sequence in vogue, since the time of Virchow, from hypercholesteremia to increased intimal lipid deposition ending in atheroma has been questioned Duguid[11] has restated the Rokitansky concept that atheroma begins in deposition of fibrin and extends by incorporation and organization of these deposits The bridge between this view and that which associates atherogenesis with lipemia is provided by experiments which show that lipemic blood may hasten coagulation in vitro or shorten plasma clotting time induced by an incomplete thromboplastin

Proteins

Dietary proteins may also be involved in experimental atherosclerosis The production of atherosclerosis in the monkey was accomplished by means of diets containing alpha protein and was prevented when casein was the dietary protein Other studies with rats showed that the hypercholesteremic response varied according to the protein level The lowest response was observed among those animals receiving the highest level of dietary protein Since atherosclerosis in man is associated with an abundant diet, it is difficult to believe that diets low in protein or low in essential amino acids can be a causative factor

The American Diet

Has there been a marked change in the American diet during the past one or two generations—a period in which the incidence of coronary heart disease and atherosclerosis may have increased?

Katz[12] states unequivocally that the fat content of the American diet has increased To prove this point, he cites data from the Department of Agriculture going back to 1910 But these data are concerned with food estimated to be available at the retail level and are really no true measure of the actual food consumed The tremendous fat collections from kitchens during the war years are an indication of the degree of the loss

The second method of estimating food consumption is the dietary survey Many studies ranging from approximately 1900 to the present day show a considerable variation in dietary intake, depending on the group and area under scrutiny However, variation with time is not very striking

It is true that the use of hydrogenated fats has increased Thirty years ago these processed fats were relatively new products However, the proportion of animal and vegetable fats in the diet has remained relatively constant It might be pointed out that an increase in the consumption of hydrogenated fats during the past 25 to 30 years does not necessarily mean a decrease in the intake of the so-called essential fatty acids The following are reasons for this

1 Although the use of hydrogenated vegetable oils has increased over the past several years, so too has the use of these same oils in their natural state This latter use represents a substantial contribution of "essential" unsaturated fatty acids

2 Gross measurements of changes of saturation induced by hydrogenation do not necessarily indicate the degree of change in the content of biologically active linoleic and linolenic acids During hydrogenation the content of normal linoleate of an oil, while reduced, is not abolished

McCann and Trulson[13] have recently estimated the intake of "essential" fatty acids in current and past American diets and comment as follows "However, there has been no marked change in the total amount of essential unsaturated fatty acids in the American diet over the past half century The increased saturation of fats induced by the hydrogenation of shortenings and margarines has been balanced by an increased consumption of 'other fats and oils,' fats which are mostly unsaturated and have a high content of essential fatty acids "

General Comment

One can summarize the hypotheses presented as follows 1 Diet may play an important role in the pathogenesis of atherosclerosis 2 The fat content and the total calories in the diet are probably important factors 3 The type of fat, rather than the total fat or the ration or balance between the saturated and certain unsaturated fats, may be the basic determinant 4 The proposition that the character of the American diet has so changed during the past 50 years as to increase the incidence of coronary vascular disease has not been supported 5 Other aspects of fat metabolism may be determinants 6 A wide variety of other factors, dietary and nondietary, may be of equal or greater importance 7 Myocardial infarction, the real crux of the problem, has been only recently, and, on a complicated dietary regimen, produced experimentally, despite the extensive and severe atherosclerosis that has been produced

It should be realized that these conclusions are subject to some very basic criticisms One is that most of the studies have focused attention on the concentrations of serum cholesterol, serum lipid, or serum lipoprotein without proper emphasis on the focus of the problem, which is atheroma and infarction Is there compelling evidence that, if we treat to adjust the serum cholesterol concentration, we are doing anything to lessen the chances of coronary infarction? Perhaps the best that can be said is that there is an association which has statistical value but that it is not an obligatory association either in small groups or, much less, in an individual

Even if one accepts the equation that hypercholesteremia leads to atherosclerosis (or some variant thereof), the fact is that serum lipid concentrations (perhaps more in some people than in others) show considerable "spontaneous" fluctuations which makes the application of the formula difficult Variations of serum lipid concentrations among individuals of the same sex and age who consume similar diets are also great Consequently, data based on single determinations are potentially highly inaccurate, and control data by repeated observation on standard regimens should be secured over several weeks

Vital statistics, particularly those from countries with different methods of reporting, understaffed health departments, and low autopsy rates are very apt to be misleading The diagnostic accuracy of all physicians is not equal, and standards vary from place to place Diet histories are time-consuming and, at best, yield data which are only moderately accurate When data are obtained through interpreters and when good rapport has not been possible, they lose even this limited value A national diet, low in fat, is usually also low in sucrose and animal protein, it is usually high in fiber and starch, and the vitamin and mineral content may differ from American diets

Finally, there are other common factors in human life which are atherogenic but are not related to lipemia Of these, the most common and best documented is arterial hypertension This association is well recognized The greatest frequency of complications of atherosclerosis, fatal and nonfatal, was found in a group of patients whose severe hypertensive disease had been brought under some control with antipressor drugs Among these persons, such complications occurred three times as often in those with high diastolic pressures (greater than 110 mm Hg) as in those with lower average pressure In the severely hypertensive patients, there was no demonstrable association between the incidence of these complications and the levels of serum cholesterol or of the light or dense lipoprotein fractions

Conclusions

Atherosclerosis and myocardial infarction are diseases in which numerous factors are involved, including diet Diet and nutrition are important factors in experimental atherosclerosis and, very probably, in the human form of the disease Thrombosis and infarction are probably more likely to occur in arteries severely sclerosed

The evidence at hand suggests a general association with high rates of consumption of fat, but it is difficult to disentangle this from caloric balance, exercise, changes in body weight, and other metabolic and dietary factors that may be involved Thus, the present evidence does not convey any specific implications for drastic dietary change, specifically in the quantity or type of fat in the diet of the general population, on the premise that such changes will definitely lessen the incidence of coronary artery disease On the other hand, the fact that obesity is a nutritional failure caused by consuming more calories than one expends and the fact that dietary fats are the most concentrated source of calories, providing some 40 to 45% of the daily caloric intake, suggests that many persons should consume fewer calories For most, this will mean eating less fat

Prudence, as well as habit and taste, will dictate the selection of a diet containing some fat Diets providing 25 to 30% of the calories from fat, rather than the current 40 to 45% in the American diet, can still provide palatable meals for our accustomed tastes

The key points of nutritional common sense for better health generally, and most likely in regard to atherosclerosis specifically, consist of a balanced, varied diet which adjusts total calories to reach or maintain a desirable weight, and which provides less fat, more protein from lean meat, fish, poultry, and cereals, and a reasonable selection of fruits and vegetables, as well as animal foods

The aforementioned conclusions obviously apply to the general population and not to patients or to individuals with a family history of early deaths from cardiovascular disease nor to those who are being followed up with some regularity by their physician The newer concepts of nutrition readily suggest various types of diet therapy which may prove useful to certain patients Investigative procedures of this type, together with continued basic research, will, in time, provide the facts upon which dietary recommendations may in the future be made to the public at large and which may help in lessening the prevalence of coronary thrombosis

REVIVING THE SURVIVORS

Each year an estimated 250,000 Americans become sufficiently disabled to require rehabilitation services Along with our increased population and longevity, we see more congenital malformations, more chronic illnesses, and more crippling conditions from accidents Yet there are at least two million physically handicapped adults who could be rehabilitated to the point of gainful employment

That picture presents a staggering view of the future Unless something is done about using the disabled, in the next generation there will be a drag of one chronically ill person, one physically handicapped person, or one unproductive oldster economically saddled upon every American worker who is able-bodied Such a prospect creates a high priority challenge to management, labor, and government—to every thinking citizen—because it foreshadows a socioeconomic crisis of first magnitude It is an even sharper challenge to the medical community, because no amount of big spending or good intentions can enable the disabled to be useful and happy again unless comprehensive medical action and planning is called into play with the efforts of interested lay groups and individuals

It is precisely because rehabilitation demands such universal concern—the concern of all physicians—that the American Medical Association's Board of Trustees last year established a committee drawn from five A M A Councils Industrial Health, Mental Health, Medical Physics, Medical Service, and Medical Education and Hospitals This Committee on Rehabilitation is presenting its first report on page 2045 of this issue of THE JOURNAL It emphasizes that "every individual physician can and should assume responsibility for the rehabilitation of his patients' by directing them to the proper specialized medical and other services in the community This, in turn, offers county medical societies the opportunity to perform another service for their members Listing of the various medical, social, and educational agencies which provide help to the disabled person within the community

The A M A committee sees rehabilitation as a total problem requiring total participation of our culture's diverse forces, including medicine, education, and sociology But in this concept of totality, the committee goes on to say, 'the physician should take the lead and direct the rehabilitation team if the important, traditional physician-patient relationship is to be maintained and his patients are to receive all the benefits total rehabilitation has to offer"

Indeed, there are great benefits, as evidenced by effective rehabilitation programs carried on by some universities, businesses, foundations, and other institutions—all via medical direction The University of Minnesota's Rehabilitation Center, for example, uses the resources of several hospitals, the graduate medical school, research laboratories, and Minneapolis-area industry to return, little by little in a comprehensively planned program, the disabled to self-sufficiency in outlook, home life, and employment Each new activity, mastered with medical supervision, becomes a part of the patient's much-needed independence when he is ready to go home

Success also is being achieved by the Liberty Mutual Insurance Company in a cooperative hospital service and two rehabilitation centers in Chicago and Boston Under the totality concept of rehabilitation, every patient receives the benefit of correct medical diagnosis, early treatment, steady care by a team of rehabilitation experts, and follow-up help by vocational training specialists The insurance company reported 'Costs of rehabilitation are more than matched by the dollar savings achieved [Our] philosophy is to go beyond treatment of the disability itself, to draw upon all of modern medicine's vast resources to the point of seeing the patient not only healed but fully functioning in our society"

In Peoria, Ill, the Institute of Physical Medicine and Rehabilitation functions in two hospitals, where medical care, social service, speech therapy, psychological testing, and job placement are combined in facilities which formerly were available only in scattered big city locations

Such a grasp of the nation's rehabilitation problem—an understanding, to begin with, that it is a many-faceted problem best solved in the home community—is being made elsewhere in the United States Exercised extensively with proper medical initiative, this grasp can help turn an enormously wasteful liability into a total asset It can enable our disabled not merely to survive but to revive

A study of disabled individuals rehabilitated through rehabilitation programs reveals that 80 to 85% of the rehabilitants continue to work, are in the same or a better job, and increase their earnings just as other workers do Studies also have shown that handicapped workers are adaptable, productive, careful, regular, reliable, and capable This pool of talent would go far to meet the increasing demands for skilled and unskilled employees in American industry In addition, it would mean savings in public assistance payments of hundreds of millions of dollars Considering that it is now costing the public more than 500 million dollars annually to provide maintenance and medical care for the disabled through public assistance programs, this item is not insignificant for the taxpayer Perhaps of greater importance, however, is the role which the rehabilitated person can assume as a public-spirited citizen and as a happy employee

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

Two disturbing suggestions that could cloud the future of voluntary health insurance in the United States are getting strong support They are the proposed Social Security amendment to provide 60 days of free hospitalization for beneficiaries 65 years of age and over and the insistence of certain labor groups on comprehensive coverage which will pay all medical care bills

Already the American Medical Association is on record as actively opposed to the 60 day-hospitalization amendment Like other recent Social Security amendments, the latest proposal is another in a line of piecemeal steps toward government control of medicine Although proclaimed as a measure to solve the hospitalization problem for older folks, it is actually a political move to capture votes—quite naturally planned for 1958, a congressional election year

I admit there is a problem of finding ways to provide voluntary health insurance for persons over 65 Although thousands who reach age 65 may continue as members of medical care plans, some plans arbitrarily drop older persons from the rolls and others reduce their benefits Too, a few plans often refuse enrollment to older people Efforts, however, are being made to resolve the issue I believe there are some promising experiments in progress For example, medical societies and others are testing "over 65' contracts and preretirement financing of health insurance for insured persons

Even though there are 118 million Americans covered by some form of voluntary health insurance and 25% of the medical bills are paid from health insurance funds, we know new plans can be devised to cover more Americans and to offer needed benefits The various experiments now in progress are testimony to the desire of medicine and its allies to provide the best possible plans for the individual

We are close to some excellent solutions to the problem of voluntary health insurance for the retired However, these plans could be nullified by a government scheme of 60 days free hospitalization If they are, the whole structure of voluntary health insurance will be weakened and, I believe, will be in danger of being 'gobbled up" by new and greater extensions of the government into the health insurance field

The other suggestion that could do irreparable damage to, or perhaps destroy, voluntary health insurance is the insistence by some labor unions on full payment for complete medical care on an insurance basis It is folly to think that insurance plans could pay all bills for all medical care of every insured individual Health insurance was never meant to relieve the insured person from any individual responsibility for financing his health care costs It was meant to improve his ability to pay for medical care needed

Under the suggested full-payment scheme there would be no built-in controls on utilization, for the insured person would have no real interest in the bills he contracted Consequently, the demand for benefits would be uncontrollable and costs would be infinite It is my opinion that no one must expect of insurance those goals which are unrealistic And full payment for all medical bills is unrealistic

Thus, I believe that the 60-day-free-hospitalization plan and the full-payment plan for all medical bills are undesirable proposals They do not provide reasonable financing mechanisms for paying for health care costs In the government proposal the financing mechanism is a direct step toward the socialization of our economy

In the labor suggestion the demands are so great as to make voluntary health insurance economically unsound Thus, voluntary health insurance would appear undesirable or unequal to the task, and the idea of complete government control of all health insurance thereby fostered

Medicine has a duty to oppose such unsound schemes It has the great responsibilty of experimenting and encouraging as broad a coverage as possible within the limits of actuarial soundness It also has the job of resisting demands of patients for unnecessary hospitalization and treatment

No one is in a better position than the doctor to help the cause of voluntary health insurance, and to promote better medical attention for more Americans while maintaining a free medical profession If we fail to grasp this opportunity we will do the insurance industry, our patients, and our profession a serious disservice

DAVID B ALLMAN, M D, Atlantic City, N J

ORGANIZATION SECTION

FEDERAL MEDICAL LEGISLATION

First Session, 85th Congress

Public Health Training and Services

Senator Humphrey (D., Minn.), in S. 2304, would amend the Public Health Service Act to provide an emergency five-year program of grants and scholarships for post-graduate education in the field of public health." He would authorize the appropriation of 1 million dollars annually, for five years, for subsidies to maintain and increase enrollments in schools of public health. A school could receive 15% of the basic operating costs of graduate instruction plus $500 for each full-time student in excess of the average past enrollment, plus $500 for each student enrolled in excess of 30 students. He would authorize also the appropriation of 1 million dollars for five years for construction and equipment of schools of public health, but grants could not exceed 50% of the total cost. The bill also contains an authorization for $250,000 annually for scholarships for a period of six years. This bill was referred to the Committee on Labor and Public Welfare.

Representative Rhodes (D., Pa.), in H. R. 6771, proposes to earmark, from funds already authorized, "an amount, not to exceed $1,000,000, to enable the Surgeon General to make grants-in-aid, under such terms and conditions as may be prescribed by regulations, for the support of public or nonprofit educational institutions which provide comprehensive professional training, specialized consultative services, and technical assistance in the fields of public health and in the administration of State and local public health programs." This measure was referred to the Interstate and Foreign Commerce Committee.

Grades of Major General and Brigadier General in the Medical Corps

Representative Durham (D., N. C.) has introduced, in H. R. 6801, a measure which would authorize the appointment of general officers in the Medical Service Corps, one of whom would be the chief of the Medical Service Corps, with the rank of major general. The appointment of two other major generals and two brigadier generals would also be authorized. This bill was referred to the Committee on Armed Services.

Federal Aid for Medical Schools and Research

Senator Smith (R., N. J.), for himself and Senator Purtell (R., Conn.), in S. 1917, and Representatives Harris (R., Ark.), in H. R. 6874, and Wolverton (R., N. J.), in H. R. 6875, have introduced identical measures which would amend the administration bill for authorizations of federal funds for five years to aid in the construction of medical school facilities. The bill would also extend the federal aid program for construction of research facilities two additional years. Thus, the two programs would terminate at the same time. They would authorize the appropriation of a total of 225 million dollars over the five-year period. Up to 30 million dollars of this would be used for the construction of dental teaching and research facilities.

Grants under this measure would not be given if the building were to be a hospital, diagnostic or treatment center, rehabilitation facility, or nursing home, as defined in the Hill-Burton act. However, schools of osteopathy or public health would be eligible for grants in the same manner as schools of medicine and dentistry. The measure specifically states that neither the federal government nor any of its officials shall interfere with the personnel, curriculum, methods of instruction, or administration of any institution. A National Advisory Council established under the Health Research Facilities law would be advisory to the federal government in the combined program. The House measures were referred to the Interstate and Foreign Commerce Committee. The Senate measure was referred to the Labor and Public Welfare Committee.

Senators Hill (D., Ala.), Kennedy (D., Mass.), Neely (D., W. Va.), Humphrey (D., Minn.), and Smathers (D., Fla.), have introduced, in S. 1922, a bill "to authorize a five-year program of grants for construction of medical and dental educational and research facilities." They would authorize the appropriation of 60 million dollars annually with 52 million a year marked for medical schools and 8 million for dental schools. The federal contribution toward construction could not exceed 50%, except in the case of existing schools which agree to increase the freshman enrollment 5% over the 1956-1957 freshman enrollment. In this case the federal grants could equal 66.6% for the cost of construction as for new schools. Schools of osteopathy would also be eligible for such grants.

No grant or grants could be made to any one medical school in excess of 3 million dollars or in excess of 1 million dollars for any one dental school. Up to 20% of the amount of any grant for any construction could, at the discretion of the applicant, be allocated to permanent endowment for maintenance of the new facility. The bill provides for a Federal Council for Medical and Dental Educational Facilities to assist the surgeon general. This measure was referred to the Committee on Labor and Public Welfare.

Representative Fogarty (D., R. I.) has introduced a similar bill, in H. R. 7841, except that the bill would authorize 45 million dollars annually for medical schools, 7 million for public health schools, and 8 million for dental schools and would limit the federal

---

From the Washington Office of the American Medical Association.

grants to 3 million dollars for any one medical school, 1 million dollars for a public health school, and 1 million dollars for a dental school This measure was referred to the Interstate and Foreign Commerce Committee

Trustees for Welfare Funds

Senator Goldwater (R , Ariz) proposes, in S 1813, to amend the National Labor Relations act to require the appointment of three trustees for welfare funds for workers One trustee would be named by the employer and one by the employees A third trustee would be appointed by the United States district court judge for the district where the fund has its principal office An audit would have to be made by a certified public accountant and filed with the Securities Exchange Commission and would also have to be open to public inspection No officer or employee or member of the fund could borrow from the fund nor share in any commission or brokerage fee paid for insurance The employer could make payments to a welfare fund of his employees only after he had received from each employee, on whose account deductions are to be made, a written assignment effective for not more than one year or the period of an applicable collective bargaining agreement This measure was referred to the Committee on Labor and Public Welfare

Presumption of Service Connection for Convulsions and Meningitis

Representative Granahan (D , Pa), in H R 6984, proposes to amend the Veterans Regulations to provide that idiopathic convulsive seizures manifesting a 10 per centum degree of disability or more within six months from the date of separation from active service shall be conclusively presumed to have been incurred in or aggravated by active service "

Representative Teague (D , Texas), in H R 7573, would provide 'that meningitis developing a 10 per centum or more degree of disability within one year after separation from active service shall be presumed to be service connected ' Both measures were referred to the Veterans Affairs Committee

Water Pollution Control Act Amendments

Representative Hiestand (R , Calif), in H R 7156, has introduced a bill to amend the Water Pollution Control Act to repeal (1) that section which authorizes the federal government to make available 3 million dollars in grants to states for establishing and maintaining adequate measures for the prevention and control of water pollution, and (2) that section under which the federal government would be authorized to make grants for water treatment plants up to a total of 500 million dollars over a period of 10 years This measure was referred to the Committee on Public Works

Federal Advisory Council on Health

Representative Wainwright (R , N Y), in H R 7171, and Senator Smith (R , N J), in S 2293, have introduced similar measures based upon the recommendations of the Commission on Organization of the Executive Branch of the Government These measures would establish a Federal Advisory Council on Health "to evaluate and advise on reorganizing the conduct of the several medical programs in respects necessary to achieve a maximum of economy and to eliminate duplications of efforts and competition among the several departments and agencies " The House measure was referred to the Interstate and Foreign Commerce Committee and the Senate bill to the Committee on Labor and Public Welfare

Health Insurance for Civilian Federal Employees

Representative O'Hara (D , Ill) has introduced, in H R 7581, an identical measure to that of Representative Lesinski (D , Mich), H R 753, and Representative Shelley (D , Calif), H R 4700, previously reported These bills would provide for withholding 50% of the cost of health insurance from the employee's salary The federal government would contribute 50% of the cost The government contribution would cease when the employee s salary payments cease However, if an employee retires on an annuity with 15 years or more of service, or is retired for disability, the federal government would pay the total cost of the plans An advisory board of federal employees or employee representatives would advise the chairman of the Civil Service Commission of the administration on the proposed law This bill was referred to the Committee on Post Office and Civil Service

Senator Scott (D , N C) has introduced, in S 2357, a bill identical to H R 7034, by Representative Holifield (D , Calif), previously reported This bill was drafted by the American Hospital Association The cost of health insurance would be borne by the employees and by the government for both basic and major medical coverage Coverage would be voluntary on the part of the employees The employees share would be paid through payroll deductions The contribution of the federal government could not exceed $1 biweekly for an employee, or $2 50 biweekly for the employee and his dependents The types of insurance from which the employee could choose would be (1) a plan for basic health benefits on a service basis and, if elected, major medical benefits as well through the same carrier, (2) basic benefits on an indemnity basis and, if elected, major medical as well, (3) a group plan of hospital, surgical, or medical benefits or any combination of such services provided by a national association of federal employees, (4) a group practice prepayment plan approved by the Civil Service Commission Employees retired after Dec 31, 1957, receiving an annuity could enroll in the plan at the same charge as other employees in their locality Survivors of the employees could also elect coverage at the same rates This bill was referred to the Post Office and Civil Service Committee

Senator Johnston (D , S C), for himself, and Senator Carlson (R , Kan), in S 2339, and Representative Rees (R , Kan), in H R 8299, have introduced the administration's bill to "provide federal contributions and authorize payroll deductions for prepaid health insurance for federal employees and their dependents" The insurance program would be a voluntary one with payroll deductions but employees must take both basic coverage and catastrophic or major medical coverage The basic health insurance plan must (1) offer coverage at group rates, (2) must not discriminate because of race, sex, or hazardous employment, (3) must accept enrollment regardless of age, or physical condition, (4) must not object to the federal employee being transferred from one agency to another, (5) must agree that an employee or his dependents shall have the right to continue coverage upon separation or retirement of the employee at rates not in excess of similar plans, (6) must furnish the employee a policy or certificate, (7) must not reduce benefits or increase premiums because of age, (8) must not exclude payment of benefits for preexisting physical conditions, except pregnancy existing on the effective date of coverage

The major medical insurance would pay 75% of covered hospital expenses after the first 70 days of hospitalization (the basic plan presumably would cover the first 70 days) Benefits would also include 75% of medical costs not covered by the basic plan after a $100 deductible payment by the employee Benefits under major medical coverage would be limited to $5,000 in any one calendar year and $10,000 in a lifetime Federal employees 65 years of age and retired employees could continue their major medical insurance plans with or without basic health insurance, and the federal government would continue making contributions toward the major medical insurance but not the cost of basic coverage after retirement The government contribution for basic health insurance would be one-third of the premium up to 50 cents biweekly for the employee or $1 50 for the employee and one or more dependents For major medical coverage the government would contribute one-third or 12½ cents biweekly for single employees and 37½ cents for employees with dependents Both measures were referred to the Post Office and Civil Service Committee

Tax Deferment for Self-Employed

Representative Latham (R, N Y), in H R 7675, proposes to amend the Internal Revenue Code so that taxpayers may deduct from adjusted gross income in calculating income tax the cost of retirement plans up to a maximum of 5% of such income or $3,000 annually, whichever is less Employed persons who are covered under a pension or profit-sharing plan could deduct only 2 5% of earned adjusted income or $3,000 annually, whichever is less More liberal deductions are permitted for persons between 50 and 70 years of age Payments from the retirement fund could not be collected until the taxpayer attains 65 years of age or unless he becomes totally and permanently disabled prior to such age

Representatives Dooley (R, N Y), in H R 7868, Hemphill (D, S C), in H R 7874, and Flood (D, Pa) have introduced measures identical to H R 9 by Jenkins (R, Ohio) and H R 10 by Keogh (D, N Y), previously reported These would permit the self-employed taxpayer to deduct from his adjusted gross income on account of retirement plan costs a maximum of 10% of his net earnings or $5,000 annually, whichever is less, and could not exceed $100,000 during a taxpayer's lifetime Between 50 and 70 years of age, an additional 10% could be deducted for each year over 50 Periodic payments made to the taxpayer from the fund after 65 years of age would be treated as ordinary income for tax purposes For earlier take down or surrender for cash, an adjusted tax would be paid All these measures were referred to the Ways and Means Committee

Public Assistance Amendments

Representatives McGovern (D, S D), in H R 7703, O'Hara (D, Ill), in H R 7879, and Bowler (D, Ill), in H R 7951, have introduced measures identical to a series of bills previously reported, amending the public assistance provisions of the Social Security Act to make more uniform state laws regarding standards of qualification for applicants and recipients of federal-state public assistance The changes in the present law would be (1) make the age requirements for old-age assistance recipients the same as that established for old-age beneficiaries of the social security "insurance" system, i e, 62 years for women and 65 years for men, (2) allow aged and handicapped recipients to earn up to $50 per month and still draw maximum assistance benefits, (3) parents of needy children could earn up to $30 as could needy children (blind recipients are already permitted to earn $50 per month without penalty of reduction in assistance aid), (4) real property up to $5,000 could be owned without loss of assistance aid, nor would ownership of personal effects up to $1,200 and household furnishings and insurance policies up to $500 of value diminish assistance payments, (5) names of public assistance recipients would be held confidential, (6) residence requirements could not be imposed on any public assistance applicant providing he lived in the state for as long as one year All the above measures were referred to the Ways and Means Committee

Hill Burton Hospital Construction

Representative Anderson (D, Mont) proposes, in H R 8053, to authorize funds which are available for construction of Indian health facilities to be used to assist in the construction of community hospitals, which are defined to include diagnostic or treatment centers, and which also will serve Indians and non-Indians The surgeon general of the Public Health Service could furnish federal funds for construction of that portion of a community health facility devoted to the care of Indians The project sponsor would be required to furnish its normal share as under the Hill-Burton program for that portion of the hospital or diagnostic or treatment center not devoted to the care of Indians A diagnostic or treatment center is defined as "a facility for the diagnosis or diagnosis and treatment of ambulatory patients—(1) which is operated in connection with a hospital, or (2) in which patient care is under the professional supervision of persons licensed to practice medicine or surgery in the State, or, in the case of dental diagnosis or treatment, under the professional supervision of persons licensed to practice dentistry in the State"

This bill was written in the Department of Health, Education, and Welfare It was referred to the Interstate and Foreign Commerce Committee and promptly reported out favorably and passed by the House of Representatives

Representative Knutson (D , Minn) has introduced, in H R 7741, a measure which would extend the Hospital Survey and Construction Act, for three additional years through June 30, 1962 This bill is identical to S 1487 by Senator Humphrey (D , Minn), previously reported This measure was referred to the Interstate and Foreign Commerce Committee

Representative Neal (R , W Va), in H R 8026, would continue to make available funds for surveys and planning under the amended Hill-Burton Hospital Construction Act This is to apply to the 1954 amendment authorizing grants for diagnostic or treatment centers, hospitals for the chronically ill, rehabilitation facilities, and nursing homes Under the Neal bill they would be allowed two additional years through June 30, 1959, to utilize the funds allotted to the states for such surveys and planning The extension which was sought by this bill was accepted in part with the enactment of the appropriation bill for the Department of Health, Education, and Welfare The provision in the appropriation act, however, extended authorization for the states to utilize allocated but unspent funds until June 30, 1958 This measure was referred to the Committee on Appropriations

Agency for the Handicapped

Representative Diggs (D , Mich), in H R 7799, has introduced a measure which would establish a Federal Agency for the Handicapped to which would be transferred all the present functions of the Office of Vocational Rehabilitation from the Department of Health, Education, and Welfare and several of the functions of the Department of Labor He would establish also a Division for the Handicapped in the United States Civil Service Commission to give assistance to handicapped persons in procuring federal employment, and would establish in the Department of Labor a Committee for the Training and Development of Placement Personnel This bill was referred to the Committee on Education and Labor

Social Security

Public Assistance for All Needy Persons —Representative Forand (D , R I), in H R 7831, would amend the Social Security Act to provide public assistance in the form of money payments or medical care to all needy persons The federal share would not be more than 80% of the total expenditures, depending upon the wealth, per capita, of each state The secretary of the Department of Health, Education, and Welfare would be authorized to establish within the Social Security Administration an Office of Public Welfare to administer the program

Disability Benefits for Widows at Age 50 —Representative Shelley (D , Calif), in H R 7834, would amend the Social Security Act to provide a widows' insurance benefits to a disabled widow 50 years of age instead of 62 years as is now provided in this law These measures were referred to the Committee on Ways and Means

Lobbying Act Amendment

Senator McClellan (D , Ark), for himself and Senators Bridges (R , N H), Anderson (D , N Mex), Purtell (R , Conn), Gore (D , Tenn), Thye (R , Minn), Kennedy (D , Mass), and Goldwater (R , Ariz), has introduced, in S 2191, a measure to amend the Legislative Reorganization Act of 1946, which requires the registration of lobbyists The administration of the act would be by the comptroller general of the United States, who would receive the registrations and police activities of lobbyists and report violations to the United States Attorney General The legislative persons subject to the Act are (*a*) legislative agents, (*b*) employers of legislative agents, and (*c*) persons or organizations who write to more than 1,000 persons asking them to communicate with Congress or make expenditures exceeding $50,000 in a year in presenting a program to the public, part of which is calculated to influence legislation A legislative agent is defined as any person who, for any consideration, is employed or retained to influence legislation, in person or through any other person, by means of direct communication The employer of a legislative agency who spends $300 or more in any calendar quarter to influence legislation must also register This measure was referred to the Committee on Government Operations

Representative Hyde (R , Md), in H R 8346, has introduced a similar measure but it would broaden the term lobbying to include communication with officers and employees of Congress, as well as members of Congress This measure was referred to the Judiciary Committee

Vocational Rehabilitation Act Amendment

Senator Magnuson (D , Wash), in S 2254, and Representative Wright (D , Texas), in H R 8429, proposes to extend the authority for grants to states and public and nonprofit organizations and agencies for planning, preparing, and initiating a substantial nationwide expansion of vocational rehabilitation programs in the states This authority was to end June 30, 1957, under the existing law Representative Wright would extend it to June 30, 1958, and Senator Magnuson would extend it indefinitely The House measure was referred to the Committee on Education and Labor and the Senate bill was referred to the Labor and Public Welfare Committee

Tax Deductions

For Rest Home Care—Representative Ashley (D, Ohio), in H R 8093, has introduced measure identical to S 1275, introduced by Senators Murray and Mansfield, (D, Mont), previously reported They would allow *in computing the income tax deduction from the* adjusted gross income of "amounts paid for the institutional care of a disabled person to be deducted as medical expenses The term 'medical care' also means amounts paid to an institution for the care (including board and lodging) and supervision of an individual who is disabled and who is in such institution because of his need for continual personal attention For purposes of this paragraph, an individual shall be considered to be disabled only if he is unable to engage in any substantially gainful activity by reason of age or of any medically determinable physical or mental impairment which can be expected to be of indefinite or long-continued duration"

Medical Expense Deduction—Representative Wharton (R, N Y), in H R 8253, would amend the Internal Revenue Code 'to remove the existing maximum limitations on the amount of the deduction for medical expenses" and would permit the deduction of all medical expenses over 3% of the adjusted gross income in calculating income tax Both measures were referred to the Ways and Means Committee

Food Additives

Representative Teller (D, N Y), by H Res 273, would establish a select committee of 10 members of the House of Representatives "to conduct a full and complete investigation and study of the use of chemicals and other additives in food, medicine, and beverages, with a view to ascertaining what deleterious effects such chemicals and additives have on human life and health' This bill was referred to the Rules Committee

Representative Harris (D, Ark), in H R 8390, would amend 'the federal Food, Drug, and Cosmetic Act to prohibit the use in food of additives which have not been adequately tested to establish their safety The pretesting data on such additives must have been fully submitted to the Secretary" for evaluation before the additive could be used The use of the additive could then be stopped by court injunction

Representative Miller (R, Neb) has introduced a similar measure, in H R 8112 Both measures were referred to the Interstate and Foreign Commerce Committee

Longshoremen and Harbor Workers' Compensation Act Amendment

Senator Magnuson (D, Wash) in S 2400, would 'amend the Longshoremen's and Harbor Workers' Compensation Act, so as to provide that an injured employee shall have the right to select his own physician' This amendment is identical to H R 7303, introduced by Representative Roosevelt (D, Calif), and reported previously in detail The injured employee could select the physician and hospital of his choice However, if the employer believed that the care being rendered is not adequate, an application could be filed with the commissioner to obtain an order authorizing treatment by another physician The employer could have the claimant examined by a physician of the employer's choice This measure was referred to the Committee on Labor and Public Welfare

Treaties and International Agreements

Representative Mason (R, Ill), in H J Res 375, proposes an amendment to the Constitution relating the legal effect of treaties and international agreements The essential provisions are 'that no treaty shall have greater effect within the United States than if it were a law of the United States, and any international agreement, other than a treaty, shall have effect within the United States only to the extent provided by a law of the United States"

Executive agreements to become effective as domestic law would have to be implemented by a law passed by both branches of Congress This bill was referred to the Judiciary Committee

JOURNAL INDEX

The index to volume 164 of The Journal will appear in the Sept 14 issue Those who wish extra copies of the index may receive them, without charge, on request to the Order Department, American Medical Association, 535 N Dearborn St, Chicago 10

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

NOTES FROM THE COUNCIL

Election of Officers

Dr Leland S McKittrick was elected Chairman of the Council to succeed Dr H G Weiskotten, who retired Dr James M Faulkner was elected Vice-chairman

Newly Approved Four-Year Medical Schools

During the course of the academic year 1956-1957, the medical schools of the universities of Mississippi, Missouri, and Saskatchewan initiated full four-year educational programs Survey of these institutions by the Council on Medical Education and Hospitals and the Association of American Medical Colleges resulted in their being granted approval All three schools had previously offered and been approved for two-year programs in the basic medical sciences

COUNCIL ON MEDICAL SERVICE

STRESS AND EXHAUSTION

Edward L Bortz, M D, Philadelphia

This is the second of a series of papers on various aspects of aging Each paper has been prepared for the Committee on Aging by an authority in the field When completed, the series will be published in booklet form

Resistance to disease becomes progressively less with increasing age Older individuals are killed by diseases which would not have destroyed them when they were young It has been stated by Alex Comfort that, had we throughout life the same resistance to stress and disease as we had at the age of 10, about half of us might expect to live approximately 700 years The object of studying the changes that occur with aging is to find out why they occur and what can be done about them

Many of the changes which take place in the body and nervous system are susceptible of reasonably exact measurement There is dispersion of energy with the passage of time This results in structural and functional alterations which are the measure of rate of aging When a tissue retains its ability to maintain optimum structure for function, the rate of physiological aging may be kept at a minimum As toxic agents and adverse environmental influences bring about a lessening of the vitality of the tissues, the rate of aging is accelerated

The aphorism "adapt or perish" emphasizes Hans Selye's suggestion that adaptability is the most distinctive characteristic of human existence Adaptation to stress is a gradual building up of resistance of the tissues to adverse factors Loss of ability to adapt is an indication of aging There are exquisite mechanisms within the body whereby it is able to neutralize the various shocks It can adapt to a wide variety of conditions Under a normal healthy state of affairs, a minimum of wear and tear and deterioration of body tissues and function occurs Insofar as an organ has adequate reserve, it can withstand ordinary assaults which would dissipate that reserve Following the recovery period in the adaptive process, the body reserve returns to normal

Selye[1] reviews, in a recent article, the various concepts bearing on the syndrome which he identifies as the stress syndrome He defines stress as a state manifested by a specific syndrome which consists of all the nonspecifically induced changes within the body The stress syndrome has a specific form even though it is nonspecifically induced The syndrome affects the whole body while the local stress syndrome influences several units within a part However, stress always manifests itself by a syndrome, that is, by the sum of the changes and not by any one particular change It is essential to understand that a specific stimulus acting only on one organ usually causes a less marked stress response than a nonspecific agent which acts in many parts of the body For example Selye points out that exhaustive stimulation or even complete destruction of a limited cell group is much less effective in causing a corticotropin (ACTH) discharge than is a moderate stimulation of a more extensive area The magnitude of the stress manifestation, that is, the corticotropin discharge, appears to depend upon the sum of all the reactions which occur in the body at any one time There must be a common pathway somewhere in response to stress These facts are important in understanding the reaction to long-continued stress states which may produce eventual alterations in structure

Exhaustion may result from physical and emotional strain or from the innumerable vexations and torments of modern times Identification of the most common causes that bring about exhaustion is helpful These may be identified as the various illnesses, functional disturbances, organic diseases, abnormal mental attitudes, and many other conditions It is important to realize that the body can neutralize the wasting of its reserve if given adequate assistance

The wear and tear reactions in the body are reflected in the variations of function which revolve around the pituitary-adrenal axis For example, 17-ketosteroid output is lowered in chronic illness, a frequent experience of the elderly Recent physiological and biochemical tests that have been studied showed no essential differences in relation to stress between normal healthy youngsters and healthy older persons In a number of conditions, such as infections and antigenic stimuli, the older individuals seem to show a more superior and efficient response to the stimulus than do the very young, especially those under 2 years of age Mortality rates from circulatory and surgical procedures are about the same for good-risk patients regardless of their age Growing old, of itself, need not impair the responses to the strains of modern existence

Each individual is endowed with an amazing margin of reserve at birth Apparently this is specific for the individual As yet, only the most crude methods are

---

Chief, Medical Service Staff B,' The Lankenau Hospital

Members of the Committee on Aging are Drs H B Mulholland Chairman Charlottesville, Va, Edward L Bortz, Philadelphia Henry A Holle, Austin, Texas, Wingate M Johnson, Winston Salem, N C, Theodore G Klumpp, New York, Frederick C Swartz, Lansing, Mich, and Cecil Wittson, Omaha Committee Staff Mr George W Cooley, Secretary and Mr Herbert B Norton Research Assistant available for studying the reserve of particular organs at the clinical level However, conditions of physical sickness are now being observed, and methods are being tried in an endeavor to estimate the reserve of particular systems such as the pulmonary tract, the heart, the arterial system, and the nervous system Exhaustion, experimentally, of certain organs such as the pancreas can produce temporary disease When the body, with the passage of time, is unable to completely renew its energy and heal injured tissues, the scar of the disease remains This stigma may be of little consequence if it occurs in a part of the body that is not vital to continued existence On the other hand, even a small clot in a blood vessel in a vital area of the heart or the brain stem might produce fatal outcome to a body that is in otherwise excellent condition As long as the individual maintains good homeostasis and thereby is capable of meeting the day-to-day stresses and strains satisfactorily, aging per se has little, if any, influence on impairing stress responses The diseases and deteriorations of tissues in older individuals embarrass physiological responses and thereby set the stage for further structural damage This is an important point, for it emphasizes the necessity for maintaining good physical fitness as a factor for long life

In long-term illnesses, especially those in which considerable wear and tear of tissues occurs, with continued stimulus of the pituitary-adrenal axis, the 17-ketosteroid output is lowered When the reserves of the body are extended in excess of energy replacement, the individual is living at a deficit He is spending more of his basic vitality than he is renewing At the particular moment in his life when the expenditure of tissue energy exceeds tissue repair, senescence has begun The rate of senescence may be demonstrated very well experimentally In animals, changes which resemble the degenerative alterations characteristic of old age may be produced in the organs by long-continued stresses The body responds in a nonspecific as well as in a specific manner to the various obnoxious agents such as infection, neoplasm, metabolic deficiency, or organ decompensation Impulses arrive at the anterior pituitary axis through the hypothalamic nuclei and through the mediation of epinephrine Next, the pituitary secretes the trophic hormones Through this mechanism there is a shift in the balance of hormone production with a relative diminution of thyrotropic and gonadotropic hormones with an increase in the production in corticotropin

From the specific hormones of the adrenal glands, effects occur in practically every organ of the body Tissue metabolism may be greatly altered The blood sugar level may fall An ulcer may develop somewhere in the gastrointestinal tract Increased capillary permeability may occur According to the adaptation reaction of Selye, these are classified as the first or alarm reaction phase In the so-called counter shock phase, a reversal of some of these effects may take place Authorities agree on the changes which take place in the structure and function of organs with advancing age There is a loss of fluid and an increased frequency of achlorhydria Frequently there is a mild loss of glucose tolerance However, the healthy older body must be much more carefully studied before it is condemned to unhappy and deficit existence

Since life entails a continual striving to attain aims, it is impossible to conceive of living without stress The objectives of an ambitious individual are only obtained by strong drive with the expenditure of energy Without some commitment of this kind there can be no stress For many authorities the terms stress, strain, and striving are practically identical Without motive there is no effort, without effort there is no strain, and without strain there is no stress Stress implies combat—combat with oneself against some tendency or habit or against some circumstances in general The time of stress may be short or long, the outcome may be unsuccessful As a rule, the individual is aware of the stress The stress itself is not so important as the depletion of energy leading to exhaustion The problem then is simplified by consideration of maintenance of adequate organic reserve that may be physical or mental Antistress factors then take on a new significance

Fatigue, like stress, is a many-sided experience, one for which an adequate definition has not been stated Fatigue refers to the condition of a body weakened by prolonged stress This may set the stage for many clinical syndromes The majority of these are referable to the circulation, the digestive tract, and the central nervous system Definite changes in the physiochemical pattern of the blood may frequently be discovered Fatigue is subjective, the patient has difficulty in performance There is a drag and increasing unwillingness on the heart, the brain, and the nervous system to respond to demand A tired person is unlikely to have any enthusiasm about anything When he is enthusiastic the fatigue disappears Weariness and boredom in oldsters are invited by lack of motivation Personal attitudes take on significances as motivation reflecting a sense of values This becomes more and more important with advancing years

Conditions which produce stress and fatigue leading to exhaustion are now being studied Their reflection in the various constituents of the blood and tissue fluids is becoming known Protective nutrition, anxiety resolving devices, and specific motivation are basic essentials These are now generally accepted Margins of reserve for each individual may be recreated that will grant him longer life and, perhaps, a more enjoyable one Improved living conditions, which are the attributes of a society highly sensitive to social responsibility in the atomic era, are capable of bringing about a deeper measure of enjoyable existence

In resisting the useless expenditure of energy, man's fight with time is his greatest battle In that battle, his emotional life—the surplus of hope over despair, of love over indifference, of motive over resignation—is highly important As Helton [2] points out, it is not a fight for the duration of the body so much as it is a fight for the duration of the capacity for happiness One can be too busy and too active in the process of maturing to be annoyed by the deteriorations of aging Purposeful activity up to the limits of physiological and mental optimum represents the most potent factor in the fight against premature human deterioration

MEDICAL NEWS

ALABAMA

State Medical Election —The Medical Association of the State of Alabama has installed the following officers Dr John A Martin, Montgomery, president, Dr Edgar G Givhan Jr , Birmingham, president-elect, Drs Hugh E Gray, Anniston, Samuel W Windham, Dothan, William D Anderson, Tuscaloosa, and Everett L Strandell Brewton vice-presidents, Dr Douglas L Cannon, Montgomery, secretary-treasurer, and Mr W A Dozier Jr , Montgomery, executive-secretary

CONNECTICUT

Rabies in Animal —Connecticut's first instance of rabies since 1949 was reported when a rabid skunk was found in New Canaan near the New York State border It was reported that rabies in foxes has for several years been a problem in neighboring New York state, west of the Hudson River, which heretofore served as a natural barrier presumably in protecting Connecticut foxes

FLORIDA

State Medical Election —The Florida Medical Association has installed the following officers Dr William C Roberts, Panama City, president, Dr Jere W Annis, Lakeland, president-elect, Dr Ralph W Jack, Miami, first vice-president, Dr Walter E Murphree, Gainesville, second vice-president, Dr James T Cook Jr, Marianna, third vice-president, Dr Samuel M Day, Jacksonville, secretary-treasurer, and Dr Shaler A Richardson, Jacksonville, editor

ILLINOIS

Personal —Dr Andrew J Toman, medical superintendent of the Bridewell for 20 years, has been named health officer of Berwyn succeeding Dr Nicholas Frankovelgia, who resigned after serving as Berwyn health chief since 1954 Dr Toman served at the Bridewell from 1932 to 1952 and from 1953 until his present appointment He was medical director of the Chicago plant of Armour & Co ——Dr Elvin L Sederlin, formerly of Helena, Mont , has been appointed director of the Adams County Department of Health He previously served as director of the local health services for the Montana State Board of Health Before going to Montana, Dr Sederlin served as director of the DuPage County Health Department ——Dr Thornton A Davis, Skokie, has been named president of the medical staff of the Ravenswood Hospital, Chicago

Mobile Emergency Hospitals —A mobile emergency hospital caravan, sponsored by the Illinois Department of Public Welfare in cooperation with the Illinois Civil Defense Agency, has had its premiere showing at the Illinois State Fair, Springfield The mobile emergency hospital contains a representative portion of all equipment and facilities for a complete 200-bed civil defense emergency hospital For display purposes, the hospital is transported in a caravan of two trucks and one passenger car for personnel

The Federal Civil Defense Administration, through the Illinois Civil Defense Agency, has allocated 132 complete 200-bed hospitals to Illinois These hospital units are stored in sealed boxes, 16 of them at public welfare institutions The boxes are to be opened only in the event of an emergency The mobile emergency hospital may be displayed in only 2,500 square feet of space, yet show all essential elements The caravan display unit will be used for training purposes at meetings of local civil defense groups, medical and nursing societies

The Illinois Department of Public Welfare is responsible for developing and training a staff of volunteers to operate a complete 200-bed hospital should a major disaster occur anywhere in Illinois Dr Frederick Plotke, chief, Illinois Public Health Service, will coordinate the emergency hospital project with federal and state civil defense agencies, the Illinois Public Aid Commission, Illinois State Medical Society, American Red Cross, Illinois National Guard, and the other medical and nursing groups

Chicago

Society News —The officers of the Chicago Society of Allergy for 1957-1958 are Dr Norman J Ehrlich, president, Dr Harold C Wagner, president-elect, and Dr Israel A Fond, secretary-treasurer

Dr Dickinson Goes to Seattle —Dr Robert H Dickinson has been appointed medical director of the Pinel Foundation Hospital, Seattle He was formerly professor of psychiatry and coordinator of clinical services at the University of Chicago School of Medicine Dr Dickinson will assume his new duties in September succeeding Dr Stanley Jackson who is entering private practice

Personal —Dr Aldo A Luisada, director, division of cardiology, Chicago Medical School, was invited by the heart associations of five South American countries to make a lecture tour commencing Aug 15 and continuing through Sept 25 The countries concerned are Peru, Chile, Argentina, Uruguay, and Brazil Twenty-two lectures will be given in the following cities Lima, Santiago, Buenos Aires, Rosario, Montevideo, San Paolo, and Rio de Janeiro

KANSAS

University News —Dr Charles M Poser has been given the rank of assistant professor of neurology and will form a new "Section of Experimental Neurology" within the department of medicine at Kansas University Medical School, Lawrence Dr Poser will continue

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health Programs should be received at least three weeks before the date of meeting of the electroencephalogram labora- continue his work at the Veterans Ad- Hospital, Winfield State Training School, Osawatomie State Hospital

University Society of Internists—The initial meeting of the Kansas University Society of Internists was held June 15 During the past year this organization was formed for the purpose of maintaining contacts between the past and present resident physicians in the department of medicine Plans call for the society to meet annually for an informal breakfast reunion and the Ralph H Major Lecture Guest of honor at the first breakfast meeting was Dr Paul Dudley White Boston, who delivered the fourth Major lectureship

Continue Polio Study—Studies of the invading effect of different strains of polio virus will be continued at Kansas University Medical School under a grant of $104,170 from the National Foundation for Infantile Paralysis The work will be directed by Dr Herbert A Wenner, *research professor of pediatrics* Associates are Dr Italo Archetti, associate professor of virus research, and Dr George R Dubes, assistant professor of pediatrics Part of the work will be directed toward investigating sites of virus multiplication in the body and the moving of virus during an infection Under a separate grant from the foundation, Dr Wenner and associates are preparing antisera to Coxsackie and Echo viruses The antisera are shipped to laboratories in the United States and foreign countries, where they are used by research teams studying these new viruses

KENTUCKY

Society News—Dr Robert W Robertson, Paducah, was recently elected president of the Kentucky Surgical Society Dr George H Rodman, Greenville, was named vice-president and Dr Charles M Bernhard, Louisville, is secretary-treasurer

LOUISIANA

Society News—The Radiological Society of Louisiana has elected the following officers president, Dr Matthew R Green, Ruston, vice-president, Dr Joseph T Brierre, New Orleans, and secretary-treasurer, Dr Seymour Ochsner, New Orleans

MAINE

Personal—Dr Adam P Leighton, Portland, has been reappointed a member of the State of Maine Board of Registration of Medicine for another term of six years, and is continuing as secretary This is his 43rd year as member and secretary of the board

Society News—At a recent meeting of the Maine Radiological Society the following officers were elected president, Dr John T Konecki, Lewiston, vice-president, Dr Irving L Selvage Jr, Portland, secretary-treasurer, Dr Francis J O'Connor, Augusta

MARYLAND

Dr Dyke Goes to Maryland—Dr Lester M Dyke has been appointed to direct the University of Maryland student health service Dr Dyke, currently director of the health services and professor of hygiene at the University of Illinois, Chicago, and medical director of the University Retirement System of Illinois, served with the United States Army Medical Corps for 26 years He retired in 1946 with the rank of colonel He will replace Dr Harry A Bishop, who will retire from the position he has held since September, 1948

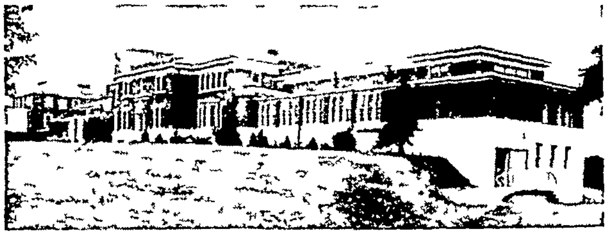
MISSOURI

Personal—Dr Willard M Allen, head, department of obstetrics and gynecology, Washington University, St Louis, received an honorary degree of doctor of science at the University of Rochester, N Y, *recently*

State Medical Election—The Missouri State Medical Association has installed the following officers Dr Walter S Sewell, Springfield, president, Dr W F Francka, Hannibal, president-elect, Dr M Pinson Neal, Columbia, Dr Paul R Whitener, Florissant, and Dr Joseph G Webster, Kansas City, vice-presidents, Dr Edward Bohrer, Jefferson City, secretary, and Dr Jerome I Simon, St Louis, treasurer

NEW JERSEY

New Building for Psychiatric Institute—The new building at the New Jersey Neuro-Psychiatric Institute, Princeton, which was dedicated recently is named after Dr Edward A Strecker, emeritus professor of psychiatry, University of Pennsylvania who has served as consultant for the Pennsylvania hospitals and consultant for the Army Air Force, and who has been appointed as the first professor of psychiatry at the Seton Hall College of Medicine and Dentistry, Jersey City The Edward A Strecker Building will serve as an admissions office, an initial diagnostic unit for inpatient services, and as an adjunct to community services at the Neuro-Psychiatric Institute Acoustical ceilings have been used throughout the building The total cost was $216,600



The Edward A Strecker building at the New Jersey Neuro-Psychiatric Institute, Princeton

NEW YORK

Dr Rioch to Give Salmon Lectures—The Salmon Committee on Psychiatry and Mental Hygiene has announced that this year's Thomas William Salmon Lectures will be given by Dr David McK Rioch, director, division of neuropsychiatry, Walter Reed Army Institute of Research, Washington, D C Dr Rioch will speak on "Research in Psychiatry Certain Problems and Developments in Multi-Disciplinary Studies at 4 30 and 8 30 p m Nov 21, at Hosack Hall of the New York Academy of Medicine

Albany Guild Formed —Catholic physicians of the Diocese of Albany met at the College of Saint Rose at the invitation of William A Scully, Bishop of Albany, to form a guild of Catholic physicians to be known as the Saint Luke's Guild of the Diocese of Albany The assembled doctors approved a constitution which had been prepared by a committee headed by Drs Clement J Handron, of Troy, John Filippone, of Albany, and Hugh Leahy, of Albany Officers of the newly formed Saint Luke's Guild, an affiliate of the National Federation of Catholic Physicians Guild, elected for the coming year are Dr Arthur J Wallingford, of Albany, president, Dr Clement J Handron, of Troy, vice president, Dr George L Marthy, of Albany, secretary, Dr William N Saint-John of Glens Falls, treasurer One of the purposes of the guild will be to offer programs in fields allied to religion and medicine

New Hospital Signalling System —An appropriation of $25,000 by the New York Community Trust will be used by the Memorial Center for Cancer and Allied Diseases to replace its present signalling system by a silent process that will send out selectively a radio impulse to any one of a maximum of 450 receivers carried by personnel of the institution The signal will be heard only by the individual to whom it is directed The area covered will include the group of buildings comprising the center

Under the projected arrangement, a radio wave emanating from the hospital's telephone room will trigger a beep beep" in the receiver carried by the person for whom the communication is intended This will direct him to the nearest telephone to obtain his message from the operator

Initial installation of 134 receivers will permit the discontinuance of an estimated 83% of the 1250 average daily pages made over the present audible system The eliminated calls will include all regular audible paging during the night hours from 10 p m to 7 a m

NORTH CAROLINA

Expansion of Pediatric Ward —Memorial Hospital at the University of North Carolina, Chapel Hill, has become the recipient of a grant of $22,000 from the Tri-Sigma national social sorority for expansion of the space and facilities for crippled and sick children in the pediatrics ward The expanded area will be named for the Robbie Page Memorial and will make possible an advanced therapy program The grant will be met by matching funds from the North Carolina Medical Care Commission A U-shaped outside terrace in the ward will be enclosed and the existing small play room walls removed in the process of reconstruction to produce a large play area, called a common room

Space for the therapy techniques, observation room, interview rooms, and other facilities will be available to aid in the children's treatment The reconstruction will add a net space of 1800 square feet to the therapy area The Memorial Fund was established in honor of Robbie who died of polio in 1951 Robbie was the son of Mr and Mrs Robertson Page of Douglaston, N Y Mrs Page was national sorority president at the time

OHIO

George Morris Curtis Lectureship —A George Morris Curtis Lectureship has been established at the Ohio State University Health Center "in recognition of Dr Curtis' leadership in the field of surgery" The lecture, to be given annually, is the culmination of the desire of many of Dr Curtis' former students and associates to establish permanent tribute to him Members of the division of thoracic surgery have made available a nucleus of $2,500 to establish the lectureship Selection of speakers will be made by a committee consisting of the dean of the College of Medicine, the chairman of the department of surgery, the chief of the division of thoracic surgery, and the secretary of the lectureship fund Tentative arrangements have been made to present the first lecture in October

Convert Children's Home to Hospital —Opportunity Home for Crippled Children, Toledo, is being converted into a hospital for the treatment of acute children's diseases The transformation, costing about $100,000, to be completed in about six months, will provide 62 pediatric beds and 18 convalescent beds The hospital will continue its rehabilitation and convalescent program for children with crippling diseases Reason for the change to a complete hospital is the decline in the need for convalescent bed care for children The east wing will be occupied by the new pediatric department and will be utilized for chronic convalescent care The cerebral palsy clinic, with its occupational, speech and physical therapy departments, will be moved to the second floor along with the laboratory and medical records room The x-ray department, now occupying the section to become surgery, will be transferred to the west wing, where additional facilities will provide for an emergency room, ambulance entrance, waiting room, doctors' room, and dietician's office

SOUTH CAROLINA

Society News —The South Carolina Society of Anesthesiologists has elected the following officers president, Dr John Doerr, Charleston, vice-president, Dr James L Duncan, Spartanburg, and secretary-treasurer, Dr J Ray Ivester, Charleston

TEXAS

Society News —Texas Industrial Medical Association has elected the following officers Dr Robert J Potts, Dallas, president, Dr Wendall H Hamrick, Houston, president-elect, Dr Max E Johnson, Austin, vice-president, and Dr Robert A Wise, Houston, secretary-treasurer —Dr Margaret Watkins, Dallas, was recently elected president of the Texas Orthopedic Association Other officers are Dr Duncan McKeever, Houston, vice-president, Dr B C Halley Jr, Fort Worth, secretary-treasurer, and Dr Edmund Cowart, Houston, 1958 program chairman

Research in Psoriasis —The department of dermatology, Baylor University College of Medicine, Houston, has announced an annual award of $1,000 for research on psoriasis Results of the research must have been presented before a dermatological medical society or published in a recognized medical journal during the calendar year The name of any applicant for the award, together with supporting data, should be submitted for consideration by Dec 31 of the same year The recipient will be determined by a committee composed of Drs Marcus R Caro, Edward P Cawley, Arthur C Curtis, Eugene M Farber, John M Knox Aaron B Lerner, and Carl T Nelson For information write Dr John M Knox, Department of Dermatology Baylor University College of Medicine Houston 25, Texas

VERMONT

University News—Approval of the establishment of separate departments of pediatrics and radiology, formerly having been divisions of the departments of medicine and surgery, respectively, at the University of Vermont College of Medicine, Burlington, beginning July 1, has been announced

WEST VIRGINIA

Postgraduate Institute—The second Postgraduate Institute, sponsored jointly by the Eastern Panhandle Medical Society and the West Virginia Chapter of the American Academy of General Practice, will be held at the Shenandoah Hotel, in Martinsburg, Sept 21-22 The general session includes the following topics and speakers

Rationality and Irrationality in Antibiotic Mixtures, Dr Count D Gibson, associate professor of medicine Medical College of Virginia, Richmond

Management of Pulmonary Emphysema Physiologic Basis and Practical Considerations, Dr John B Hickam associate professor of medicine, Duke University Durham, N C

Cholesterol—And Vascular Disease Dr John H Hodges assistant professor of medicine Jefferson Medical College Philadelphia

Pharmacologic Horizons—An Avalanche of New Drugs John C Krantz Jr, Ph D head, department of pharmacology University of Maryland, Baltimore

Peripheral Vascular Disease—Diagnosis and Treatment, Dr Louis M Krause, professor of clinical medicine, University of Maryland, Baltimore

Three separate sessions have been arranged for Sept 22 pediatrics, obstetrics, gynecology Application has been made for a credit of nine hours in category I for academy members Information may be obtained from Dr Halvard Wangee, General Chairman, Box 175, Shepherdstown, W Va

GENERAL

Muscular Dystrophy Grants—Recent allocations totaling $134,280 96 to support research in muscular dystrophy have been made by Muscular Dystrophy Associations of America, Inc, for scientific studies Of this sum, $26,460 was appropriated for a new research project and $107,820 96 for renewed or additional aid for 12 studies already under way The new grant-in-aid for research at the University of Pittsburgh is to Dr Thaddeus S Danowski, professor of research medicine, for 'muscular dystrophy studies" An additional $2,000 grant supplements the present research being conducted by Dr Gilbert H Glaser at Yale University School of Medicine, New Haven, Conn, where a renewal grant of $7,610 36 has been made to Melvin V Simpson, Ph D Additional grants-in-aid for continued scientific studies have been renewed at the University of Wisconsin Medical School, Madison, $11,988, Harvard University Medical School, Cambridge, Mass, $4,860, University of Illinois College of Medicine, Chicago, $6,987 60, University of Rochester School of Medicine and Dentistry, N Y, $16,135, University of California Medical Center, Los Angeles, $13,400, Western Reserve University, Cleveland, $7,452, University of Oklahoma School of Medicine and University Hospitals, Oklahoma City, $7,074, Columbia University College of Physicians and Surgeons, New York City, $12 474 and $3,240 (two grants), New York University Washington Square College of Arts and Science, New York City, $14,600

Prevalence of Poliomyelitis—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated

	Aug 3 1957		Aug 4 1956
Area	Paralytic Type	Total Cases	Total Cases

Personal —In recognition "of accomplishments in Pan American fellowship and public health, and in appreciation of their long service to the organization' honorary membership certificates were presented by the United States—Mexico Border Public Health Association to the following Dr Donald Davey, assistant director, division of local health services, California Department of Public Health, Dr Fred L Soper, director, Pan American Sanitary Bureau, Washington, D C, Dr Ignacio Morones Prietom secretario, Secretaria de Salubridad y Asistencia Mexico, D F Mexico, Dr Manuel E Pesqueira, sub-secretario, Secretaria de Salubridad y Asistencia, Mexico D F

Allergy Foundation Awards —The American Foundation for Allergic Diseases has announced awards of $500 quarterly or summer scholarships to 20 medical students from approved medical schools throughout the United States and Canada to encourage young students to broaden their knowledge in the field of the allergic diseases by research and clinical training These awards were made possible by a grant to the foundation by the Gustavus and Louise Pfeiffer Research Foundation

The students selected were nominated by the deans of their respective medical schools in collaboration with the heads of basic science departments at these institutions The awards were made by the board of trustees of the foundation on recommendation of its Scientific and Educational Council The purpose of the awards is to expose the student to experience in the basic sciences related to allergy and to broaden the application of this knowledge through clinical experience The American Foundation for Allergic Diseases, with headquarters at 801 Second Ave, New York City, was established late in 1953, not only to promote medical education and research in the field of allergic diseases, but also to expand public education in this area

Surgeons Meeting in Chicago —The 22nd annual congress of the United States and Canadian Sections of the International College of Surgeons will be held Sept 8-12 in the Palmer House, Chicago The program includes the following symposiums Injuries of the Lumbar Spine, Eye Muscles, and Lacrimal Apparatus Foreign speakers include Dr A K Saha, Calcutta, India, Dr John Charnley, Manchester, England, Dr Jesus V Tamesis, Manila, Phillippines, and Dr Ronald Jarman, London Panel discussions include the following topics and moderators

Myringoplasty and Tympanoplasty for the Improvement of Hearing in Non-Otosclerotic Conductive Losses, Dr George Shambaugh Jr, Chicago
Poliomyelitis and the Role of the Otolaryngologist in Its Management, Dr George A Saxton Jr, Chicago
Tumors of the External Ear, Glomus Tumors, Acoustic Neuromas, Dr John Lindsay, Chicago

A special symposium to be conducted Sept 12, will consider the medical problems of the Navy, particularly those arising out of the atomic age Besides a general assembly there will be section programs in the following Coloproctologic surgery, neurosurgery, obstetrics-gynecology, occupational surgery, ophthalmology-otolaryngology, orthopedic surgery, plastic and reconstructive surgery, and urologic surgery For information write Dr Ross T McIntire, Executive Director, International College of Surgeons, 1516 Lake Shore Drive, Chicago 10

Obstetricians and Gynecologists Meet —The 68th annual meeting of the American Association of Obstetricians and Gynecologists will be held Sept 5-7 at the Homestead, Hot Springs, Va The presidential address will be given by Dr F Bayard Carter, Durham, N C and the Joseph Price Oration Sept 5 by Dr Magnus Haines, chief of pathology, Chelsea Hospital for Women, University of London School of Medicine The prize thesis of the American Association of Obstetricians and Gynecologists Foundation, Inc, will be given by Dr Harry S McGaughey Jr on 'The Placental Transfer in Normal and Toxic Gestation" The program includes the following topics to be given by invited speakers

Closure of the Incompetent Cervix During Pregnancy, Dr Robert H Barter, George Washington University School of Medicine, Washington D C
Microscopic Anatomy of the Fetal Membranes, Dr David N Danforth, Evanston, Ill
Cervical Stump Carcinoma, Dr Robert N Creadick Duke University School of Medicine, Durham, N C
Conservation of Ovarian Tissue at Radical Surgery for Carcinoma of the Cervix, Dr Milton L McCall Louisiana State University School of Medicine, New Orleans, La
The Team Approach in Endometrial and Cervical Neoplasia, Dr John A Wall Texas Medical Center, Houston Texas

A motion picture session is scheduled for the afternoon of Sept 5 at which Mr John Howkins, Mr Keith Vartan and Mr Alistair Gunn, Gynaecological Travellers of Great Britain and Ireland, will make presentations The banquet will be held the evening of Sept 6 For information write Dr E Stewart Taylor, 4200 E Ninth Ave, Denver 20, Colo

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

ALABAMA *Examination* Montgomery, June 17-19 Sec, Dr D G Gill, State Office Building, Montgomery 4

ARIZONA * *Examination and Reciprocity* Phoenix, Oct 16-18 Exec Sec, Mr Robert Carpenter, 826 Security Bldg, Phoenix

ARKANSAS * *Examination and Reciprocity* Little Rock, Nov 7 Sec, Dr Joe Verser, Harrisburg

CALIFORNIA *Written Examination* Sacramento, Oct 21-24 *Oral Examination* San Francisco, Nov 16 *Oral and Clinical for Foreign Graduates* San Francisco, Nov 17 Sec, Dr Louis E Jones, 1020 N St, Sacramento 14

COLORADO * *Reciprocity* Denver, Oct 8 *Examination* Denver, Dec 3 4 Exec Sec, Mrs Beulah H Hudgens, 715 Republic Bldg, Denver 2

CONNECTICUT * *Examination* Hartford, Nov 12-14 Sec, Dr Creighton Barker, 160 St Ronan St, New Haven *Homeopathic Examination* Derby, Sept 10 Sec, Dr Donald A Davis, Derby

Delaware *Examination* Dover, Jan 14-16 *Reciprocity* Dover, Jan 23 Dr Joseph S McDaniel, Professional Bldg, Dover

District of Columbia * *Reciprocity* Washington, Sept 9 *Examination* Washington Nov 12-13 Deputy Director, Mr Paul Foley 1740 Massachusetts Ave, N W Washington, D C

Florida * *Examination* Miami, Nov 24-26 Sec Dr Homer L Pearson, 901 N W 17th St, Miami 36

Georgia *Examination* Atlanta, Oct 8-9 *Reciprocity* Atlanta Oct 10 Sec, Mr Cecil L Clifton 111 State Capitol, Atlanta 3

Idaho *Examination and Reciprocity* Boise, Jan 13-15 Ex Sec, Mr Armand L Bird, 364 Sonna Bldg, Boise

Kentucky *Examination* Louisville, Dec 9-11 Sec, Dr Russell E Teague 620 South Third St Louisville 2

Maine *Examination* Portland, Nov 12-14 *Reciprocity* Portland, Nov 12 Sec, Dr Adam P Leighton, 192 State St Portland

Maryland *Reciprocity* Baltimore, September *Examination* Baltimore, Dec 10-13 Sec, Dr Frank K Morris, 1211 Cathedral St, Baltimore

Massachusetts *Examination* Boston, Jan 14-17 Sec, Dr Robert C Cochrane, 37 State House, Boston

Michigan * *Examination* Lansing, Oct 9-11 Exec Sec, Dr E C Swanson, 118 Stevens T Mason Bldg, Lansing 8

Minnesota * *Examination and Reciprocity* Minneapolis, Oct 15-17 Sec, Dr F H Magney, 230 Lowry Medical Arts Bldg, St Paul 2

Mississippi *Reciprocity* Jackson, December *Examination* Jackson, June Asst Sec, Dr R N Whitfield, Old Capitol, Jackson 113

Montana *Examination and Reciprocity* Helena, Oct 1-2 Sec, Dr Thomas L Hawkins, 555 Fuller Ave, Helena

Nebraska * *Examination* Omaha, June Sec, Mr Husted K Watson, Room 1009, State Capitol Bldg, Lincoln 9

Nevada * *Examination and Reciprocity* Reno, Sept 3 Sec, Dr George H Ross, 112 North Curry St, Carson City

New Hampshire *Examination and Reciprocity* Concord, Sept 11-13 Sec, Dr John S Wheeler, 107 State House, Concord

New Jersey *Examination* Trenton, Oct 15-18 Sec, Dr Patrick H Corrigan, 28 W State St Trenton

New Mexico * *Examination and Reciprocity* Santa Fe, Nov 18-19 Sec, Dr R C Derbyshire, 227 East Palace Ave, Santa Fe

New York *Examination* Albany, Buffalo, New York and Syracuse Dec 10 13 Sec, Dr Stiles D Ezell, 23 South Pearl St, Albany 7

North Carolina *Endorsement* Morehead City, Oct 12 Asst Sec, Mrs Louise J McNeill, 716 Professional Bldg Raleigh

North Dakota *Examination* Grand Forks, Jan 9-12 *Reciprocity* Grand Forks, Jan 12 Sec, Dr C J Glaspel, Grafton

Ohio *Endorsement* Columbus, Oct 1 *Examination* Columbus, Dec 17-19 Sec, Dr H M Platter, 21 W Broad St, Columbus 15

Oklahoma *Examination* Oklahoma City, Dec 14-15 Sec, Dr E L Lester, 813 Braniff Bldg, Oklahoma City

Oregon * *Reciprocity and Endorsement* Portland, Oct 3 5 *Examination* Portland, January Exec Sec, Mr Howard I Bobbitt, 609 Failing Bldg, Portland

Rhode Island * *Examination* Providence, Oct 3-4 Administrator of Professional Regulation, Mr Thomas B Casey, 366 State Office Bldg, Providence

South Carolina *Examination* Columbia, Dec 10, Sec, Dr H E Jervey, Jr, 1329 Blanding St, Columbia

South Dakota * *Examination* Sioux Falls, Jan 21-22 Exec Sec, Mr John C Foster, 300 First National Bank Bldg, Sioux Falls

Tennessee * *Examination* Memphis, Sept 25-26 Sec, Dr H W Qualls, 1635 Exchange Bldg, Memphis 3

Texas * *Examination and Reciprocity* Fort Worth, Dec 5-7 Sec, Dr M H Crabb, 1714 Medical Arts Bldg, Fort Worth 2

Utah *Examination* Salt Lake City, July 9-11 Director, Mr Frank E Lees, 324 State Capitol Bldg, Salt Lake City 1

Virginia *Reciprocity* Richmond, Dec 4 *Examination* Richmond, Dec 5-7 Address Office of the Secretary, 631 First St, S W, Roanoke

Washington * *Examination* Seattle, Jan 13-15 Sec, Mr Thomas A Carter, Capitol Bldg, Olympia

Tyndall, Martha Winifred ⊕ Westfield, N J , University of Vermont College of Medicine, Burlington, 1933, at one time a member of the state board of health, served on the staffs of the Muhlenberg Hospital in Plainfield and the Rahway (N J) Memorial Hospital, died June 22, aged 62, of multiple myeloma

Wagner, Joseph Ralph, Palacios, Texas, Rush Medical College, Chicago, 1895, past-president of the school board, for many years city health officer, on the staff of the Bay View General Hospital, where he died May 28, aged 87, of cerebral thrombosis

Warmer Charles Andrew ⊕ Redondo Beach, Calif , University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903, fellow of the International College of Surgeons and the American College of Surgeons, served on the staff of the Presbyterian Hospital-Olmsted Memorial in Los Angeles, died April 9, aged 80, of coronary occlusion

Wescott, Royal James ⊕ Everett, Wash , University of Wisconsin Medical School, Madison, 1936, veteran of World War II, member of the staffs of Providence and General hospitals, died June 4, aged 47

Westcott, Niles ⊕ Oak Lawn, R I , Yale University School of Medicine, New Haven, Conn , 1909, member of the American Psychiatric Association, served as assistant superintendent of the Rhode Island Hospital and the Butler Hospital, both in Providence, died in Warwick May 31, aged 76, of diabetes mellitus and arteriosclerosis

Wharton, James Osman ⊕ McAllen, Texas, Physio-Medical College of Texas, Dallas, 1906, member of the American Academy of General Practice, served as secretary of the Hidalgo-Starr Counties Medical Society, city health officer, member of the staff of the McAllen Municipal Hospital, where he died May 27, aged 77, of pulmonary emphysema and myocardial infarction

Wheeler, Samuel Edward, Columbia, S C , Medical College of South Carolina, Charleston, 1913, veteran of World War I, died in the Columbia Hospital June 4, aged 67

Wilkerson, Jesse Bert ⊕ Brevard, N C , Memphis (Tenn) Hospital Medical College, 1906, on the staff of the Transylvania Community Hospital, died April 28, aged 75, of Hodgkin's disease

Wilson, Norman Dickey ⊕ Jackson, Mich , Georgia College of Eclectic Medicine and Surgery, Atlanta, 1913, associated with the W A Foote Hospital, died June 13, aged 85, of acute pulmonary edema

Wolf, Roy Milton, Canon City, Colo , Kansas City (Mo) University of Physicians and Surgeons, 1921, died May 19, aged 75

Wood, Wilson Guyon, New York City, Columbia University College of Physicians and Surgeons, New York City, 1906, served in France during World War I, for many years associated with the New York Hospital, died in the Manhattan General Hospital June 17, aged 77, of congestive heart failure

Woomer, Albert, Cashtown, Pa , Kentucky University Medical Department, Louisville, 1904, an associate member of the American Medical Association, also a lawyer, died in the Annie M Warner Hospital May 28, aged 82, of cerebral thrombosis

Wronker, Harry ⊕ Rochester, N Y , Long Island College Hospital, Brooklyn, 1915, member of the American Academy of General Practice, veteran of World War I, member of the medical board of the Jewish Home and Infirmary and the Highland Hospital, where he died June 7, aged 64

Young, Charles Houston ⊕ Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1906, veteran of World War I, died in the Presbyterian Hospital May 26, aged 77

Young, Frank Walker, Colonel, U S Army, retired, San Antonio, Texas, Medical College of Alabama, Mobile, 1912 service member of the American Medical Association, veteran of World War I, entered the medical corps of the U S Army as a first lieutenant in January, 1920, rose through the various ranks to that of colonel in July, 1943, retired May 31, 1945, died in the Brooke Army Hospital, Fort Sam Houston, April 18, aged 67, of encephalomalacia

Young, James Clint, Jonesboro, Ark , University of Nashville Medical Department, 1891, Vanderbilt University School of Medicine, Nashville, Tenn , 1891, on the staff of the St Barnard Hospital, where he died April 24, aged 90

Zee, Urban Herbert ⊕ Mankato, Minn , Creighton University School of Medicine, Omaha, 1937, veteran of World War II, medical director of the Mankato Rehabilitation Center, on the staffs of St Joseph and Immanuel hospitals, died March 28, aged 44

Zuckerman, Louis Herman, New York City, University and Bellevue Hospital Medical College, New York City, 1907, member of the Medical Society of the State of New York, retired chief of the Bronx Bureau of Contagious and Infectious Diseases, New York City Health Department, died in the Flower and Fifth Avenue Hospitals May 13, aged 70, of Parkinson's Disease

FOREIGN LETTERS

AUSTRIA

Early Diagnosis of Tubal Carcinoma—At the meeting of the Austrian Society for Gynecology and Obstetrics in June, J Froewis and H Kremer reported on a patient in whom a definite diagnosis of tubal carcinoma was established by clinical observation and by cytological examination A Halter stressed the significance of a clear amber vaginal discharge in diagnosing tubal carcinoma A 60-year-old woman with postclimacteric bleeding was admitted to the speaker's ward Colposcopic and palpatometric findings were normal, but curettage showed histological evidence of an atrophic endometrium The patient left the hospital A follow-up examination was made six weeks later A typical clear amber discharge and a negative cytological examination were noted Despite the negative findings, a laparotomy was performed because of the presence of a typical carcinomatous discharge Bilateral carcinoma, limited to the tubal wall, was found The tubes were only moderately enlarged, but they were completely occluded St Skamnakis said that, unfortunately, the typical amber discharge is present in only 20% of the patients with tubal carcinoma Unilateral cramp-like pain in the lower abdomen and bleeding are more frequent findings These symptoms, associated with palpable swellings of the adnexa, however, may lead to a false diagnosis of pelvic inflammatory disease and prolonged conservative treatment

Roentgenography of the Breast as Test for Pregnancy—At the same meeting, K Fochem and G Nank said that the female breast shows changes of the tissue, not only during pregnancy but also during the menstrual cycle These changes are histologically characterized by budding of the lactiferous tubules Systematic examinations were carried out during the menstrual cycle and pregnancy The roentgenogram of the normal breast shows a fine, marble-like pattern The delicate ramifications of the septums of the connective tissue include homogenous parenchymatous areas The roentgenographic changes in the breast during the menstrual cycle are minimal During pregnancy, on the other hand, a characteristic thickening of the septums of the connective tissue and clouding of the parenchyma are observed This is of diagnostic importance because the earliest of the changes can be recognized four weeks after conception In 104 patients with early, doubtful, and ectopic pregnancies or with some type of tumor, a definite diagnosis was established in 97 A false-positive reading was made in three patients, in two, diagnosis could not be made because the breasts were too small, and in two, the changes were associated with a corpus luteum cyst Owing to the high degree of correlation, roentgenography of the female breasts was recommended as test for pregnancy

R Bayer said that roentgenographic changes in the female breast ranged from a demonstrable delicate marking in the structure of the connective tissue of the breast in the phase of hormone deficiency (menopausal breast) through an increasing swelling of the corpus fibrosum in the phase of luteinizing hormonal activity of the marked swelling in the breast during pregnancy Knowledge of these changes is important in diagnosing diseases of the mammary glands and of the breast tumors The speaker stressed the fact that temporarily and quantitatively increased hormonal secretions (as in monophasic cycles or in phases of hyperfollicular internal secretion) give findings that are difficult or impossible to distinguish from the roentgenograms of the breasts made during pregnancy The speaker doubted, therefore, that the practical evaluation of roentgenograms of the female breast as a test for pregnancy is possible

COLOMBIA

Tuberculosis in Colombia—At the meeting of the 11th Pan-American Congress of Tuberculosis last May at Medellin, Abad and co-workers reported on the 25 year-old campaign against tuberculosis in Columbia Before 1932 there was no tuberculosis hospital in the country Now there are 2,355 beds in 14 such hospitals It has been estimated that about 20,000 persons have tuberculosis in this republic of nearly 13 million inhabitants In 1945 there were 40 deaths per 100,000 from this cause Ten years later the figure had dropped to 24 8 In 1948 the morbidity was 160 per 100,000 and in 1955 about 100 The highest incidence is found in the 20-to-30-year-old age group, where it is 110 per 100,000, and the lowest incidence is in the 10-to-14-year-old age group, where it is 20 per 100,000 In the over 40-year-old age group the incidence is 80 per 100,000 Clinicoanatomic types of the disease were found to differ quantitatively, depending on where the examinations were made At tuberculosis dispensaries the distribution was minimal cases, 22%, moderately advanced, 34%, and far advanced, 44% At institutions where tuberculosis investigation was compulsory, the distribution was minimal, 40%, moderately advanced, 48%, and far advanced, 12% In Colombian mortality tables, tuberculosis is in the 17th place, but in first place are deaths from unknown causes The authors believe that tuberculosis must undoubtedly be a major component of this category

At the same meeting, Tovar-Acosta of Bogotá read a paper based on 2,674 patients admitted to the Hospital Sanatorio Santa Clara during the years 1952-1956 Of these patients, 87% had tuberculosis Only five patients (0 21%) had had BCG vaccination, 9%

The items in these letters are contributed by regular correspondents in the various foreign countries

mentioned contact with a human source of infection The speaker believed this low figure was due to poor epidemiologic survey methods A positive serologic test for syphilis was found in 5% of the tuberculous patients The symptoms were grossly parallel to the severity of the disease, as classified by the standards of the United States Tuberculosis Association, but there were many far advanced cases with slight symptoms and a few minimal ones with severe symptoms Far advanced disease was found in 53% of the patients, moderately advanced in 31%, and minimal in 16% The symptoms were slight in 23%, moderate in 34%, and severe in 43% These figures are similar to those found in other tuberculosis institutions in this country They show that the diagnosis is not being made early enough Active tuberculosis was present in 80% of patients and positive sputum was present in 61% Lack of natural resistance in Colombians was demonstrated by the prevalence of diffuse lesions in one or both lungs (68%) Both diffuse and localized lesions were more common in the right lung The preponderance of caseous pneumonic lesions (57%) over all others without cavity formation (43%) also indicates a lack of resistance

Complications were encountered in 25% of cases, including 6% laryngeal, 4% pleural, 3% intercurrent diseases, 2% intestinal, and 10% genitourinary and nervous system involvement and others The hospital mortality (24%) could be blamed on poor treatment, but the speaker believes this is due, mainly, to lack of sound preventive measures Treatment has been useless in the 53% of the entire series who left the hospital while their disease was still active

INDIA

Acetazolamide—S N Sen Gupta and co-workers (*J Indian M A* 28 11, 1957) gave acetazolamide by mouth to 43 patients for whom a diuretic drug was indicated Of these, 29 had heart disease, 7 had hepatic edema, 4 had nephrotic edema, and 3 had nutritional edema The daily dose was 125 to 250 mg according to the age of the patient and was given for three consecutive days If the response was good it was continued for four more days Good diuresis developed in 23 patients The response varied in the different groups of patients, 65 5% of all cardiac patients responded well to the drug and 83% of those with cor pulmonale showed improvement One patient besides showing a good diuresis also had relief from anoxic symptoms Of the patients with hepatic edema, only 2 (29%) responded well, 14 patients in the whole series showed toxic side-effects, and 3 of these died in coma Three of these patients suffered from hepatic cirrhosis and one had gross nutritional edema with possible involvement of the liver Twenty-one patients were given a mercurial diuretic parenterally before or in place of acetazolamide treatment for comparison The mercurials were on the whole better diuretics, and their action was probably potentiated by the other drug even when given 48 hours previously The authors concluded that acetazolamide has a definite place in the treatment of heart failure and may be regarded as an alternative or adjuvant to mercurial diuretics in the treatment of this condition, but it is definitely dangerous in patients with chronic liver disease

Detection of Ovulation—P N Wahi (*J Indian M A* 28 12, 1957) stated that their previous study of vaginal smears, endometrial biopsy specimens, and urinary pregnandiol led them to conclude that the changes indicative of ovulatory and anovulatory cycles were clearly observed from the 14th to 26th day in a regular menstrual cycle of 28 to 30 days They therefore believed that a single vaginal smear on the 24th to 26th day would assist in determining the nature of the cycle The presence of urinary pregnandiol may be considered as a direct evidence of progesteronic activity (ovulation) A concurrent study was undertaken of single vaginal smears (premenstrual), endometrial biopsy specimens, and quantitative estimation of urinary pregnandiol from 80 sterile women Cases of primary sterility with a normal menstrual cycle of 28 to 30 days were selected Only one smear was taken on the 24th to 26th day An endometrial biopsy specimen was obtained on the same day, and the chemical estimation of urinary pregnandiol was done in a 24-hour specimen The results showed that ovulatory smears corresponded well with histological findings and pregnandiol secretion in 85 4% of the patients Histological examination failed in 8 3% and cytological examination failed in 2 08% of the patients with an ovulatory cycle In those with an anovulatory cycle, 64 3% of the smears were in agreement with the biopsy findings and urinary pregnandiol Histological examination failed to indicate an anovulatory cycle in 21 4% of the patients, and cytological examination was unsuccessful in 14 3% The authors concluded that the single vaginal smear method offers a fairly accurate method of determining the presence or absence of ovulation The advantage of this method is that it is simple, relatively quick, inexpensive, and can be used on a large scale

Public Health in Mysore—The Minister of Health in Mysore, while outlining his program for the second Five-Year Plan period, said that the best form of rendering preventive and curative services in rural areas was by establishing health units where those two services could be combined With this end in view, he proposed to start 102 primary health units The government accepted the plan of operations drafted by the World Health Organization (WHO) and the United Nations International Children s Emergency Fund (UNICEF) whereby those two organizations would provide two experts in maternity and child welfare and nursing administration and would supply the equipment necessary for various welfare centers in the state The two experts had already reported and were engaged in a survey of maternal and child health services, including pediatrics, available in the state Nursing facilities were also being surveyed WHO and UNICEF had already supplied much equipment Under this scheme it was contemplated to open two laboratories for chemical and food analysis These laboratories would serve not only medical and public health departments but also were open to medical practitioners in the area to facilitate early diagnosis and proper treatment The bed strength in the existing health unit dispensaries was proposed to be increased by 250 beds Five more district laboratories to undertake bacteriological, pathological, and chemical examinations were proposed to be established

Campaign Against Substandard Drugs—The Drug Standard Control in Bombay state continued to make steady progress in the first quarter of 1957 The intelligence branch attached to the Drugs Control Administration was engaged in the investigational work relating to the manufacture and sale of spurious drugs During the quarter under report, 62 investigations were made, 24 prosecutions were launched for various offenses, and 4 convictions were obtained Large quantities of drugs were destroyed because they were not of standard quality Of 1,306 samples tested, 248 were of substandard quality There were 58 licenses for manufacturing nonbiological products, 597 licenses for selling nonbiological products, 45 licenses for manufacturing biological products, and 343 licenses for selling biological products granted during the quarter under review In the same period, 126 applications for licenses were rejected, 86 licenses were revoked, and 112 manufacturing premises and 2,063 selling premises were inspected The additional staff recently authorized for the Drugs Control Administration will help to stabilize the control of drug standards in all parts of the state

Xeroderma Pigmentosum—Behl and Sachdev (*Ind J Dermat Venereol* 23 2, 1957) stated that xeroderma pigmentosum is a rare dermatological entity and they were unable to find any published records of this disease occurring in India They reported three cases which are the first probably to be seen in dark-skinned patients The first was a boy aged 17 years, an only child He started with freckles on his face at the age of 10 years and came to the hospital for a tumor on his face His face, the upper part of his chest, and his hands showed freckles, telangiectasia, and atrophic areas resembling senile skin There was a typical epithelioma on the right side of his nose which proved to be a squamous celled epithelioma A few keratotic nodules were present on his face and chest The second case was a boy aged 11 years who started getting freckles on his face, chest, and forearms at the age of 18 months Later atrophic areas and telangiectasis appeared At the time of examination, his whole body was involved with dark pigmented patches and freckles, stellate telangiectasia, atrophic areas, and keratotic nodules For three months prior to admission an epitheliomatous lesion had been developing on his left forearm His left eye showed keratitis and blepharitis with complete loss of vision This patient is the second of five children The third case was the fourth child of the same parents who since the age of 2 years had had freckles on his face, neck, hands, forearms, and legs A few areas of atrophy and telangiectasis were also present He was 4 years old at the time of examination and no lesion resembling a tumor was seen The first two cases were referred to the surgical department for excision of the epithelioma The prognosis is grave in all these cases

Action of Local Anesthetics on the Uterus—Y K Sinha (*J Indian M A* 29 1, 1957) stated that cocaine and procaine have a stimulating action on the smooth muscle of the uterus He compared local anesthetic action of such other agents as lignocaine and cinchocaine on the uterus All experiments were carried out in vitro The stimulant action of local anesthetics on the uteri of cats, rabbits, and guinea pigs was confirmed This effect seems to be due to a direct action on the muscle, as it is not antagonized by atropine, mepyramine, F 933, or hexamethonium The stimulating effect is reduced by lowering the concentration of calcium ions in the Tyrode solution Thus it may be related to ionic changes in the muscle membrane The stimulant action is not related to the local anesthetic activity Procaine, however, failed to stimulate the nonpregnant uteri of guinea pigs and the immature uteri of rabbits

SWITZERLAND

Symposium on Aldosterone—The University Clinic for Therapeutics organized the First International Symposium on Aldosterone in June The lectures and discussions will be published in detail in a special volume by Churchill Ltd, London Moonlenaar and Querido (Leyden) described a new method for the physicochemical determination of aldosterone, based on the colorimetric reaction of 2-4-dinitrophenylhydrazine with aldosterone The method is reliable and the absolute values correspond to those obtained by the method of Simpson and Tait Neher (Basel) consistently found aldosterone in large amounts in three patients with Conn's syndrome, in one patient the corticosterone level was equally high The content of aldosterone in the adrenal tissue was normal in two patients with Cushing's syndrome, whereas cortisone and hydrocortisone levels were increased Analyzing the tissue of one patient with almost complete necrosis of the adrenals, but with the preservation of the zona glomerulosa, Neher found an abundance of aldosterone This confirms the belief that aldosterone is synthesized in the glomerular zone

Desaulles (Basel) compared the biological effects of aldosterone in adrenalectomized rats with a proprietary glucocorticoid preparation (Cortexone) and hydrocortisone Contrary to the observations in man, aldosterone improved the delayed diuresis of adrenalectomized animals The action of aldosterone on the connective tissue is also different from that of Cortexone The actions of aldosterone resembled, in particular circumstances, more those of hydrocortisone than those of Cortexone Gross (Basel) stated that the maintenance dose of synthetic d-1-aldosterone is 1 7 to 2 times larger than that of the natural aldosterone He concluded that the therapeutic margin of aldosterone is wider than that of Cortexone He stated also that less potassium was lost by treatment with aldosterone than by treatment with Cortexone Furthermore, aldosterone produces hypertension only when the doses are relatively much larger than those of Cortexone. Giroud (Montreal) reported that, in a series of experiments in vitro, aldosterone is essentially produced in the glomerular zone in rats and oxen, whereas hydrocortisone is synthetized in the fascicular zone and corticosterone in both. Extracts of the anterior lobe of the pituitary stimulate chiefly the production of hydrocortisone whereas those of the posterior lobe have a marked influence on the secretion of aldosterone. Pure vasopressin and oxytocin are inactive. A contaminant must, therefore, be contained in these extracts.

Simpson and co-workers (London) studied the metabolism of aldosterone marked with tritium (H^3) in position 16. Aldosterone appeared to be more rapidly metabolized than hydrocortisone. The authors believe that the daily secretion of aldosterone is about 200 Gm. They found aldosterone in the urine in an easily hydrolyzable form at pH 1. At present, the structure of the conjugate of aldosterone is unknown, but preliminary experiments suggest a conjugation with a sulfate in position 18 or 21. This product, however, corresponds only to 5% of the amount of aldosterone produced daily by the organism. Bartter (Bethesda, Md.), stated that he produced variations in the intravascular space in experimental animals either by infusions of concentrated albumin or by repeated bleedings. The variations of aldosteronuria observed supported the hypothesis that changes in the intravascular space regulate aldosterone production. These same changes seem also to influence the aldosteronuria in the cases of secondary hyperaldosteronism. Muller (Geneva) had studied the daily aldosterone cycle in normal subjects. The elimination of aldosterone, which is increased during the day, depends essentially on the upright position and the daily activity. The deposit of sodium does not seem to influence the nyctohemeral cycle of aldosterone production. Patients with a hypophysial deficiency show daily rhythmic aldosterone fluctuations in the level only when given cortisone and when erect and active.

Garrod (London) stated that adrenal hypertension and motor paralysis are predominant symptoms of Conn's syndrome. All the patients had hypokalemia, hypernatremia, alkalosis, polyuria, hyposthenuria, and alkalinuria. Histological examinations of the kidney revealed vacuolation of the renal tubules. The secretion of aldosterone is variable, but hypokalemia is generally associated with extremely low aldosterone levels. The absence of edema remains a mystery. Stanbury (Manchester) reported that hypokalemia leads to renal insufficiency and, on the other hand, renal diseases may be complicated by hypokalemia. Renal insufficiency may become worse if associated with a depletion of potassium. Primary aldosteronism as well as Cushing's disease may produce hypokalemia associated secondarily with renal insufficiency. Depletion of sodium in patients with renal insufficiency produces, in its turn, secondary hyperaldosteronuria, which makes the depletion of potassium worse. Mach (Geneva) discussed a 37-year-old woman with idiopathic edema associated with hyperaldosteronuria. He was able favorably to influence the clinical course by repeated water overload. Wolff (Munich) stressed the disastrous effects of physical exercise on the retention of sodium by the increase of aldosterone in patients with secondary hyperaldosteronism associated with hepatic cirrhosis and cardiac insufficiency. When the cardiovascular condition is improved by rest and cardiotonics, aldosterone production decreases and the edema disappears.

UNITED KINGDOM

Tuberculosis in Pathology Laboratory Workers.—Tuberculosis as an occupational hazard of pathology laboratory workers was investigated by Reid (*Brit. M. J.* 2:10, 1957). Although the possibility of aerial dissemination of micro-organisms from sectioned pathological material has been demonstrated, the ultimate test is the demonstration of a higher incidence of tuberculosis among those working in pathology laboratories than among other comparable groups of workers. Reid first analyzed the claims for sick pay under the Health Service and found that pathologists, like thoracic surgeons and chest physicians, had claim rates for incapacitating pulmonary tuberculosis in excess of those of other medical workers and that laboratory technicians had much higher rates than other medical auxiliaries. Because of possible fallacies in interpreting the data Reid investigated the incidence of tuberculosis among the staffs of 345 laboratories in the Public Health Laboratory Service over a period of five years. It was found that the incidence of incapacitating pulmonary tuberculosis was, for different laboratory categories adjusted for age and sex, two to nine times greater than the corresponding rates in the country as a whole. The rates for pulmonary tuberculosis among pathologists and technicians were found to be two to three times greater than those of post office workers of similar age and social and economic status.

The highest rates occurred among workers employed in laboratory and mortuary tasks exposing them to the risk of contact with infected material; the incidence was highest in the second and third years of employment. In these groups the attack rate was three times that of nonexposed laboratory staff. Preemployment examination showed that young laboratory recruits had no unduly frequent previous contact with tuberculous subjects. The possibility was investigated that these high tuberculosis morbidity rates were due to factors such as overcrowding, poor physique, and better reporting than elsewhere, but these factors were not found to be significant.

Another study suggested unexpected sources of tuberculous infection in laboratory workers. Tomlinson (*Brit. M. J.* 2:15, 1957) showed that infected air-borne particles are released when screw-capped bottles containing slant cultures are opened. This is probably due to the film of fluid round the rim of the bottle becoming contaminated when the culture is inoculated. Bacteria then grow in this site during incubation and are released in a shower of fine infective particles when the bottle is opened. Another source of infection occurs when screw-capped bottles are centrifuged. This results in contaminated spray being spread over a distance of 3 ft. or more from the centrifuge. Other possibilities of infection are spray arising from incised tuberculous material and the cage dust of tubercle-infected laboratory animals This suggested that exposed laboratory staff should be tuberculin tested and BCG vaccination offered to negative reactors, that periodic roentgenograms of the chest be taken, and that potentially infected material should only be handled by experienced staff members under a well-ventilated hood

Professional Secrecy —The traditional policy of professional secrecy is likely to be reaffirmed at the British Medical Association's annual meeting at Newcastle-upon-Tyne Prof A P Thomson points out in the July issue of the *Practitioner* "In a hundred years no allegation of infamous conduct involving a breach of the rule of secrecy has ever been brought to the General Medical Council' If, however, a physician discovers evidence that warrants serious suspicion of murder or rape, he should, unhesitatingly, disclose it to the police because he has a duty to society as well as to his patient Attempted poisoning should be reported Unfortunately, a poisoner is rarely convicted on account of evidence obtained in the case of his first victim It is not the duty of physicians to assist the police in the detection of minor offences If, after a drunken brawl or other disturbance which has not entailed loss of life, the police are searching for offenders, it is not required that physicians report injuries which suggest that the patient has participated in the disturbance

Dr L J Witts says that the ban on the use of physicians names in television and radio broadcasting cannot be supported, although it is part of the present policy of the General Medical Council and the B M A Fan mail rarely includes requests for consultation Most correspondence after broadcasting comes from the lunatic fringe The public has no use for anonymous information B M A resolutions do not bind the profession, but physicians who break them are placed in an uncomfortable position

Independent Health Service Proposed —An independent British medical service was outlined at the British Medical Association's annual meeting It may be an alternative to the National Health Service or work side by side with it The scheme put forward by Dr H H D Sutherland consisted of the following proposals 1 The service should be free from political party control 2 It should be financed partly by contributions by the patient, partly through insurance, and partly by the government 3 It would provide certain specified life-saving drugs free, other medicines would be paid for by the patients 4 Participating physicians would have the right to engage in private practice This would be encouraged by the existence of a list of free life-saving drugs and necessary dressings 5 Physicians would possibly be paid on a fee-for-service basis 6 The service should be under the control of a politically independent board or corporation responsible to the privy council 7 Provision should be made for care of the old and poor without their having to pay Summing up the advantages to the public, Dr Sutherland said there would a reduction in cost to the nation and a consequent uction in the income tax There would be greater freedom of choice of physician, an improved patient-doctor relationship, and a greater sense of responsibility in patients Such a scheme would take at least five years to introduce

Tranquilizers Causing Anxiety —Physicians, worried about the possible coming of the perfect tranquilizer, warned of its probable evil social effects at the scientific meeting of the British Medical Association Even the existing tranquilizers carry many dangers, including sudden death and various complicating illnesses Dr E H Kitching, of Manchester, told of the American druggist who had to put up a "sold out" sign He had run out of tranquilizers and the queue outside his shop had to be sent away Tranquilizers are big business They have become a social habit in some com munities In 1956, American druggists filled about 30 million prescriptions for these drugs, compared with 10 million the previous year, 50,000 million tablets of one popular tranquilizer were sold in 1956 Physicians are finding that the performance of these drugs is much inferior to the claims made for them In a survey of 8,200 patients with anxiety states, physicians reported that the benefit produced by tranquilizers was small compared with the dangers There have been four deaths, including two suicides One in five patients was made worse by taking the drugs It was rare for patients to feel better beyond the first week or so Dr R Orton, of Newcastle, said there was a difference in the reaction to these drugs in men and women Women, especially if they used tranquilizers for long periods of time, gained much weight

Dr Louis Minski said that the danger of the perfect tranquilizer would be that the patient would be prepared to accept anything The sexual pervert taking it would have no sense of guilt, married couples living in slums and overcrowded quarters would accept the conditions and children would be brought up in them Prof Charles Robb, of London, said the best tranquilizer of all is whisky It is an extremely good drug for reducing postoperative pain and helping patients to sleep

Physicians Oppose Drugs for Blood Pressure —Sensible living is the way to avoid dying from high blood pressure This was the advice given by a panel of experts at the British Medical Association's scientific meeting at Newcastle-upon-Tyne So called miracle drugs are not the answer Physicians should stop frightening peo ple Most patients with high blood pressure have no need for fear, but fear can aggravate their condition Dr Robert Coope, of Liverpool, said that the "normal sheep" could not be separated from the "hypertensive goats by a couple of numerical readings Most people with asymptomatic hypertension will be alive at 65 years of age or more Even where there are such complications as minor strokes, the giving of drugs is often a substitute for proper care of the patient The man consumed with ambition, the one who burns his candle at both ends, should learn some practical philosophy and accept his limitations Dr John Hunt, secretary of the College of General Practitioners, said the family physician should reassure the patient by pointing out that hypertensives live 20 or 30 years and that one-third of them die of something quite different

The patient has to adjust himself to his high blood pressure as others have adjusted to various handicaps There should be more sleep and quiet week ends without too much strenuous exercise He lets his patients eat as much red meat as they like There is no evidence that this increases the blood pressure There is one antifear drug that has been known to man for centuries —alcohol A glass of sherry or a whisky and soda before dinner, or a nightcap, is an accepted social custom and does not make a man feel like an invalid The speaker did not believe that we are living in an age any more dangerous than those that have gone before, but the regular consumption of drugs, seducing people into a bogus tranquility in the midst of a crazy sort of life which they refuse to change, is at the root of most of our troubles Prof John McMichael, of London, said muscular activity tends to reduce blood pressure and that exercise in moderation is a good thing for hypertensive patients

WORLD HEALTH ORGANIZATION

Poliomyelitis —The Expert Committee on Poliomyelitis met in Geneva in July Under the chairmanship of Sir Macfarlane Burnet (Australia), it has come out strongly in favor of large scale trials of a new vaccine prepared from a living virus which has been attenuated so that it is no longer capable of causing the disease although it may be expected to provide lasting protection against it The live-virus vaccine can be given orally instead of being injected Preliminary trials of this vaccine carried out by several different research teams have failed to reveal any signs of illness or other harmful effects either in the persons vaccinated or in members of their families The experts consider, therefore, that the vaccine may now safely be given larger-scale trials

They do not, however, suggest that this vaccine should displace the Salk type of killed-virus vaccine in those countries where it is now being used or is about to be used They believe rather that the new vaccine should be an adjunct to the present vaccine, though it might eventually replace it if that is found desirable or be a substitute for it where the use of the Salk vaccine is not feasible If the proposed trials of the live-virus vaccine prove successful, it is hoped that the immunity it provides will be reliable and long-lasting and will result in the elimination or at least in a substantial reduction of the virulent strains of virus in circulation at present The present killed-virus vaccine cannot achieve this kind of result The committee emphasizes, however, that the most stringent precautions should surround proposed trials of the new vaccine In order to prove its complete harmlessness it should first be given to limited numbers of selected groups of persons Furthermore, the properties of the attenuated strains of virus used in the vaccine should be measured in a number of different laboratories These trials should be accomplished on a voluntary basis and with the approval of the local authorities concerned The object of the proposed trials of live-virus vaccine and the need for carrying them out are based on the belief that they may go far in further reducing the prevalence of poliomyelitis in the world

Experience with Salk Vaccine —The committee also reviewed the experience gained in those countries where killed-virus vaccine has been used In France vaccination was not officially started before June 1, 1956 Several million doses were released, but, since most of them were exported, a close follow-up of results will be possible only for about 800,000 vaccinations Of these, 100,000 had been given up to July 1, 1957, with negligible side-reactions In Poland, the average mortality from poliomyelitis in the years 1951 to 1954 was 6 3% of the reported cases More males (55%) than females (45%) caught the disease, and the highest incidence was in the group infancy to 4 years of age (78% of all cases) In 1957 Poland began to produce the vaccine, and in October it is planned to vaccinate 100,000 children in Warsaw and Lodz

In Great Britain vaccination has not offered complete protection against poliomyelitis, as some cases of paralytic disease were observed in vaccinated children After the incidents which occurred during the first large-scale vaccinations in the United States, the authorities decided to manufacture a modified form of the Salk vaccine, the type 1 Mahoney strain of virus being replaced by a less virulent one In Canada, the lower incidence of poliomyelitis in the last two years has made it difficult accurately to evaluate the results of the vaccination program In 1956, 11 cases of paralytic poliomyelitis were reported among a total of 1,860,000 vaccinated children and 136 cases in 2,140,000 unvaccinated children of similar age In Southeast Asia the incidence of the disease has remained low Cases among the adult population are almost unknown except among foreigners In the United States, 15,400 cases occurred in 1956 This represents a rate of 9 2 per 100,000 population and is the lowest recorded since 1947 Because of the wide annual variations in incidence, it has not been possible definitely to attribute the low incidence in 1956 to the widespread use of vaccine (70 million persons were vaccinated) In Israel all children from 6 months to 3½ years of age were vaccinated between January and May, 1957 This was done because it was found that over 80% of paralytic cases occurred in that age group Among emigrants up to the age of 40 years from Western Europe and the Americas it was possible to vaccinate 130,000 persons

In the Union of South Africa vaccination campaigns began in 1955 and were continued through 1956 and 1957 During this period the country experienced a prolonged and severe epidemic, which, for the first time, affected Africans as much as people of European descent, but among the Africans the disease affected young children for the most part, while in the Europeans older children were also affected and there were many cases among adults About 500,000 children have been vaccinated In Russia there was a distinct rise in the incidence of the disease in 1955 (8 cases per 100,000 population) Available information indicated no reduction in 1956 or 1957 Young children under 7 years of age were most affected (85% of cases) In the spring of 1957, 80,000 children were vaccinated In Sweden large-scale vaccination campaigns were begun in February, 1957, and 800,000 persons have been vaccinated No cases of poliomyelitis after inoculation have been reported

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Malpractice Statute of Limitations—The plaintiffs, husband and wife, filed an action for damages caused by the alleged malpractice of the defendant physician From a judgment in favor of the defendant, the plaintiffs appealed to the district court of appeal second district, division 3, California

On June 15, 1952, the wife was injured in an automobile accident She had been under defendant's care for about two years for a suspected gallbladder condition, and shortly after the accident she again engaged the defendant s services She was placed in a hospital on three occasions, but at no time during the course of treatment did the defendant treat her for injuries suffered in the accident From the time after the accident until the following January the plaintiff wife suffered from extreme pains in her head, dizziness nausea and impairment of vision The defendant, however, attributed this condition to ailments from which she had previously suffered Although x-rays were taken, they did not suggest to the defendent that the condition that was causing the wife s suffering was an accumulation of fluid that was creating brain pressure and injury to the optic nerves The physician-patient relation between the plaintiff wife and the defendant was terminated Jan 6, 1953, and on defendant's recommendation, she then consulted Dr Seletz who informed the plaintiffs on Jan 9 that there was an increased pressure within the wife s head due to a head injury and that he feared it was a surgical condition but one he believed he could remedy On Jan 17, Dr Seletz told the plaintiffs there was another test (an air study) that should be made and that this study would not be made without an understanding beforehand that if, in his opinion, surgery was indicated he had permission to proceed immediately The plaintiffs agreed When the wife entered the hospital on Jan 17, a writing was prepared which stated in part Mrs Jewell Calvin, Dr E Seletz, subdural hematoma—preoperative diagnosis, possible subdural hematoma " Dr Seletz testified that the diagnosis was written by him and that he signed the paper The plaintiffs signed a paper which read, in part "preoperative diagnosis, possible subdural hematoma" This was over the signature of Dr Seletz On Jan 19, the wife signed a paper which read, in part "operation and anesthetic record preoperative diagnosis, shaving of head" The wife testified that the papers were signed by her in blank The papers containing the diagnosis however, stated that the signers certified that the diagnosis was written in before the operation and Dr Seletz testified that he wrote in the diagnosis, that he never operated without writing in the diagnosis, and that to the best of his knowledge it was written in before the plaintiffs' signatures were attached The present action was filed Jan 28, 1954

The defendant contended that the action was barred by the one year statute of limitations The plaintiffs, however, contended that the evidence was not sufficient to sustain the finding that they had knowledge of the facts constituting their cause of action more than one year prior to the institution of the action The evidence showed that the information conveyed to the plaintiffs by Dr Seletz before and after the operation was such that they must have known that the defendant had not made a correct diagnosis nor given the wife the care her condition required The plaintiffs did not deny that Dr Seletz made it clear to them on Jan 19 and 20 that the defendant had made an incorrect diagnosis The statute began to run when the plaintiffs acquired knowledge of the facts constituting their cause of action The physician-patient relation was severed prior to that time and the defendant did nothing thereafter to interrupt the running of the statute or to estop him from relying on it In the opinion of the court of appeals, the trial court could not reasonably have found that the plaintiffs did not have knowledge of the facts constituting their cause of action as early as Jan 19, 1953 Since the action was not filed until more than a year later (Jan 28, 1954) it was barred by the statute of limitations Accordingly, the judgment of the lower court in favor of the defendant physician was affirmed *Calvin v Thayer, 310 P (2d) 59 (Calif, 1957)*

Chemical Tests for Intoxication Self-Incrimination—From a conviction for driving a motor vehicle while under the influence of intoxicating liquor, the defendant appealed to the criminal court of appeals of Oklahoma

The defendant testified that, following her arrest, she was taken to a room in the police station where she was told to blow her breath into a balloon, to walk a line, to pick up some coins, and to perform other manual tests She said that she thought she had to do everything the officers told her to do because she was under arrest She testified that the officers refused to allow her to make a telephone call for advice, failed to tell her of her right to counsel and to refuse to do the things demanded, and did not advise her that the evidence could be used against her The prosecution offered no evidence to rebut that of the defendant The court said that a confession of a defendant shown to have been induced by hope or promise of benefit or through fear is involuntary and inadmissible The defendant's evidence that she performed the tests because of fear was not denied and must be given full credence The tests were, therefore, not voluntarily performed

The defendant contended therefore that the admission of evidence as to a drunkometer test and the other involuntary tests denied her the privilege against self-incrimination guaranteed by article II, section 21 of the Oklahoma constitution The privilege against self-incrimination, said the court, was established in the common law to protect the individual against the employment of legal process to extract from his own lips an admission of his guilt The cases from the various states are uniform in holding inadmissible self-incriminating words forced from the lips of an accused or forced incriminating writings, but they are not uniform as to evidence obtained by use of bodily fluids of an accused gotten either while he was unconscious or when he was conscious but against his will Likewise as to other forms of physical evidence The reason for the rule that distinguishes between "real and "physical' evidence is that where evidence is elicited from the lips of an accused or by writings, where such evidence is given either in fear of punishment or in hope of escaping punishment, such evidence is not admitted because experience shows that the accused is liable to be influenced by these motives, and such evidence cannot be relied on as guides to truth This objection does not apply to evidence of the nature complained of in the present case, because no hopes or fears of the accused could change the physical facts one iota The court therefore held that the admission of evidence as to the involuntary tests did not violate the defendant's privilege against self-incrimination

The defendant also contended however that it was error to allow the officer who performed the drunkometer test to testify as to the results of the Harger color change test, which he obtained from reading the gasometer cylinder of the drunkometer, because he was not an expert in chemistry and was unable to independently work out the formula involved In a prior Oklahoma case it was held that for the results of the tests to be admissible there should be the following (1) proof that the chemicals were compounded to the proper percentage for use in the machine, (2) proof that the operator and the machine were under the periodic supervision of one who has an understanding of the scientific theory of the machine, (3) proof by a witness who was qualified to calculate the reading of the machine into the percentage of alcohol in the blood The officer performing the test did not meet the third requirement, but that link was supplied by a physician who qualified as an expert This expert testified that a person having the amount of alcohol in his blood that the defendant had would be under the influence of alcohol

It must be recognized in giving the tests for the alcoholic content of the blood that the color-change test of both the Harger drunkometer, and the intoximeter (Forester) used by the highway patrol and mentioned by the defendant, require no knowledge of chemistry or mathematics, nor is it necessary to understand the meaning of the operations in order to obtain the percentage of blood alcohol reading But it does require a chemist to make the further tests where the dehydrite tube and ascarite tubes are used in case of the drunkometer and magnesium perchlorate tube and the ascarite tube in case of the intoximeter And it does require an expert witness to testify as to the meaning of the readings That was done in this case Certainly the drunkometer could not be cross examined as to the reliability of the reading, but there was ample opportunity to cross examine the operator as to whether an unused balloon was used for trapping the breath, whether the pipet for measuring the potassium permanganate and the separate one for measuring the sulfuric acid were clean, and whether the rubber tubes connecting the various parts were leak-proof, etc It was only necessary to determine that the machine was in working order, that a careful reading was made, that the exact amount of chemicals was measured out, that the air was shut off at the instant the color change took place, and, after a course of instruction, that the operator was qualified to make the test in question All this was done, also

The court pointed out that it was not holding that a drunkometer test, standing alone, would be sufficient to sustain a conviction Persons who observed the defendant following her arrest testified that in their opinion she was intoxicated There was also testimony that she staggered off the straight line all four times she tried to walk it and that she had great difficulty in picking coins up from the floor When given the Romberg test she swayed very badly The court concluded that there was ample evidence to support the verdict of the jury The judgment of conviction was accordingly affirmed *Alexander v State, 305 P (2d) 572 (Okla, 1956)*

Malpractice Patient's Fall from Examination Chair — This was an action for damages for injuries caused by the alleged negligence of the defendant physician The trial court sustained the defendant s general demurrer so the plaintiff appealed to the court of appeals division 1, Georgia

The plaintiff suffered an eye condition which resulted in a partial loss of sight and went to the office of the defendant physician for treatment In treating the plaintiff for the condition, the defendant had her sit in a chair which could be raised or lowered as desired After placing a medicament in the plaintiff's eyes, he raised the chair and left the room After having been left alone for about 30 minutes, the plaintiff attempted to get down from the chair, tripped, and fell It was the plaintiff's contention that the defendant, knowing she had defective eyesight, was negligent in leaving her unattended, in a dangerous and exposed physical position, and in failing to warn her against attempting to get down from the suspended position without assistance

Section 84-924 of the Georgia Code requires a physician to use reasonable care and skill in the practice of his profession, and ordinarily the question of whether a physician has used that degree of skill is a question for the jury However, said the court, where from the allegations of the plaintiff's petition it is palpably clear that the injuries complained of were not caused by the failure of the physician to use reasonable care and skill but rather from the independent act of the plaintiff, the question should be decided as a matter of law where a timely general demurrer has been filed The judgment of the lower court was accordingly affirmed *Robinson v Campbell, 97 S E (2d) 544 (Ga, 1957)*

MISCELLANY

AMERICAN MEDICINE ABROAD—TANSEN, NEPAL

Lou Hazam

This is the third of a series of on-the-scene reports from the "March of Medicine" production team, which is traveling around the world to film an hour-long television program on the work of American doctors abroad—the services they perform, the conditions they face, the personal satisfaction they receive in their unofficial roles as America's medical diplomats The author, Mr Lou Hazam, has written all but one of the "March of Medicine" scripts since the series started in 1952 In this article, he tells of the dedicated work of Dr Carl Friedericks in Tansen, Nepal Also on the "March of Medicine" itinerary are such places as Hong Kong, Sarawak, Burma, Korea, India, Ethiopia, Lebanon, Turkey, and Guatemala The program, sponsored and produced by Smith, Kline & French Laboratories in cooperation with the American Medical Association, will be seen in color next spring over the NBC television network —Ed

There is a good chance that we have found the American doctor who is serving in the most remote and inaccessible region of the world We believe that that doctor is Dr Carl Friedericks whom we visited in Tansen, Nepal

North of India, in the towering foothills of the earth's highest mountains, the Himalayas, Dr Friedericks cannot be reached by plane, train, car, or boat—but only by days of the most arduous climbing over steep and primitive mountain trails, fording streams, and crossing plains two days, at least for the uninitiated, from the small, thatch-roofed town where the last conveyance, a rickety bus, deposits you

First, to come by the route we followed, one must fly over the chain of mountains known as the Maha Bharat range to reach the capital of Nepal, which is Katmandu This is an experience in itself Recently, when late out of Burma I sought to rejoin the Smith, Kline & French March of Medicine" crew which had already preceded me there, it called for rising at dawn in Calcutta, boarding an Indian Airlines plane, and setting out for an ancient crossroad of civilization, dating back to the time before Christ, known as Patna Here the idea was to board another plane for Katmandu In the sweltering heat of the airport, one waited three and a half hours for this departure, and finally—piloted by two handsome bearded Indian pilots—took off and pointed to the north

What followed was, in a sense, a bright nightmare All went well until we reached the mountains that since the dawn of man had stood as a formidable barrier between India and its neighbor In vain did the pilot, skirting between the towering cliffs, seek to find his way over them, only to be frustrated by the mist that overhung them, hiding the highest peaks He circled and tried again and again, to no use Finally, he turned and made his way to an "airport" nearby [illegible]? It was a flat field, with no runway, covered by solemnly grazing cattle Undeterred, the pilot put his plane down with a jolt, as the cattle, frightened by the noise, ran for cover as we rolled in the direction of a thatched adobe structure that I supposed was the "terminal"

The faces of the people who quickly collected were strange and fascinating We remained there for about 10 minutes, and then, as the rain began to fall in huge droplets, the pilot cried "Let's go!" It was easy to understand why, for if we stayed much longer we would be mired in a sea of mud and never be able to take off Quickly he pulled out the stones he had placed under the wheels of the plane, and with a roar we were air-borne again

This time it was clearing "upstairs" The plane banked in the direction of the mountains that loomed ahead and we now were apparently going to challenge them In a moment they were on either side of us ridge after ridge rising far above the wings of the plane in a succession of obstacles Picking out a sort of valley path, the pilot wound his way through them, turning a corner occasionally and entering another pass, as all the while there unfolded all around us the most striking scenic grandeur—a splendor that was so all-enveloping, that one forgot to be afraid At last we came over terraced slopes, planted to their very peaks, and then with a swoop we were over the major valley the fertile plain, once a lake bed, on which the capital city of Katmandu had stood for centuries, and now appeared to come rushing toward us

This much, compared to what was to follow later, was nothing Only I did not know it then Plans had already been made to depart for Tansen the following morning to film the medical work of Dr Carl Friedericks I had arrived just in time to secure a visa and join the party (Yes, in Nepal one needs a visa to move from the Katmandu region to another part of the country In short, one needs a visa to travel within the borders of the same country!) Preparations were significant Food, water, bedding, mosquito nets, guide—all had to "laid on" before venturing forth into the very special world that lay ahead I stood innocently by, suspecting nothing We were to divide our crew Two were to remain behind—Charles Paulton, our sound engineer, for lack of batteries and the difficulty of hauling his equipment in any case, and Mike Oppenheimer, our associate producer, to clear the way for future travel Making the trip to Tansen were to be David Lowe, our producer, Ian Struthers and Geoffrey Gurrin, cameraman, and myself

Next day, again at the crack of dawn, we took off from Katmandu for Pokhara Once more—this time seated on bucket seats, the baggage piled at our feet—we rose from the valley which soon spread out below us and headed for the hills, which gradually grew more forbidding After 30 minutes or so we reached and put down at Pokhara to deposit passengers and take on others, plus more baggage Again the heat—suffocating In a short while we emplaned once more, and this time, once we were up, the mountains put on a real show!

Apparently what we had been referring to as mountains before must have been merely giant molehills For suddenly the clouds cleared, and there behind the highest dark range towered the hugest snow covered peaks I had ever seen . . . monster-sized mountains that sent a wave of excitement through the whole plane.

‘There, look quickly,’ cried the steward. “Annapurna!”

Annapurna—26,492 ft. high! Was not this the mountain that struck fear into the hearts of even the most courageous mountain climbers? I wondered what madness had brought us anywhere near it, and while I tried to enjoy the view as long as it lasted, I was somewhat relieved when the clouds pulled their first-act curtain over it again.

And now we were at our last plane stop, Bhairahwa. Here was a village with the faint shadow of a road snaking away from the airport. We were still miles from our starting place, and what was needed now was a bus to carry us as far as it could, i.e., as far as roads went, before we set out by foot. Fortunately, Dr. Friedericks had received news of our plans by government wireless from Katmandu. An emissary, Earl Schmidt, long, strong, and lanky, showed up with a bus which must have been discarded by the Smithsonian Institution as too old, dating back most certainly to the beginning of the motor age. We piled in, not without doubts, and after some hand-cranking and motor coughing we set off with four drivers! (I learned en route what they were for. One cleared the road of stony obstructions and tested the bridges, another constantly ran ahead to the nearest stream of water to fill the radiator, and the third spelled the driver and kept the motor lubricated with oil.)

It was a journey none of us will ever forget, and its end was as full of surprises as its beginning. For the village at which we ultimately found ourselves was huddled at the foot of mountains that almost surrounded it. Here in Butwal we were to move our luggage from the bus to the backs of porters, mountain climbers almost from the day of their birth.

To see these wiry men pack, to watch them lift the huge loads to their backs, supported by a strap that passed over their foreheads, and then actually bend under the load and walk with the pack intact, left us all weak. So began the trek.

Never, as long as memory remains with us, will the two days that followed be lost to our family and friends. We were all city-born, desk-broken. To walk even to our cars was an effort. Now we were taking on mountains. The land rose gradually at first, then abruptly. Carefully we picked our way along, armed against the heat by big black umbrellas we had thoughtfully purchased on the way. In a matter of moments we left the last semblance of town behind us and were now enveloped, as the home-sitting poets put it, in the arms of nature.

And such arms! Stones the size of houses . . . paths suitable only for mountain goats . . . deep gorges . . . rushing mountain streams to be forded . . . and inevitably ahead, more of the same . . . and always up . . . up. Worn and weary beyond previous experience, the first night on the trail we spent in a rude hut where a nice woman, decorated by rings in her nose and gold jewelry in her ears, made us a Nepali dinner—hot as the chili of Mexico. We stretched out on mats under mosquito nets and slept until dawn.

Again we continued on, crossing another high ridge that called for not looking over the side while we walked. The scenery must have been beautiful, but with our eyes mostly on our feet, we missed a great deal of it. At one point we were met by a groom and horse, sent to us by Dr. Friedericks. We took turns with this sure-footed animal, and in time hired the services of two more we came across in a mountain village preparing to make the crossing with sacks of rice. As the day wore on, again and again we paused for breath and water. We used a Swiss filter pump to make the water drinkable and chlorine pills to kill the bacteria.

We finally entered a great plain planted with rice. Here and there a farmer urged on his water buffalo, pausing only momentarily to stare at the strange procession that passed him. At last, there loomed before us, still some miles ahead, the city of Tansen, hugging the mountainside in the distance. At first we despaired, then took courage and moved on—not with “renewed vigor,” however, for we had little vigor left. We camped at the base of the final hill and rested for an hour. And then we turned to face the last hurdle, an incline that appeared to rise straight up at a 90 degree angle.

It was our great good fortune that, when we had barely begun to climb this hill, Dr. Friedericks, astride a grey horse, appeared with a shout and a hello. A true gentleman, he dismounted—after our greetings were over—and insisted on one of us taking over his animal as he himself walked alongside. It did not take much persuading.

The above saga is recounted here simply to demonstrate the remoteness of the place that Dr. Friedericks has chosen to practice medicine. Now as to the man himself.

Carl Friedericks calls Reading, Pa., home. He is 36 years old and graduated the University of Pennsylvania Medical School in 1945, under the wartime accelerated program. He interned at the Robert Packer Hospital at Sayre, Pa. After a short jaunt with the Army (“I'm afraid my Army service was plush. I only fought the battles of New Jersey, Texas, and California.”), he went to China on October, 1947, to Canton and Yeoung Kong as a medical missionary. By June 24, 1950, he was out again.

“The Communists had come in the previous October—nine months before,’ he said. “It was just obvious that I was a handicap to the people. In addition to the personal danger that seemed to threaten, I was lonesome for my family that I had sent out earlier—to Korea to be safe! And being American, I was a source of embarrassment to my friends and hospital staff—it was becoming difficult for them to deal with me.”

And so Dr. Friedericks moved from China to India, where he remained a year and a half. During this time, he took his first trip to Nepal with Dr. Robert Fleming, an ornithologist who had been there previously on a bird-collecting expedition for the Chicago Natural History Museum. It was while he was on this trip that he saw the tremendous needs of the people medically. Several influential citizens requested him to start a hospital there. Application was made to the government, and when he returned to the States again in April, 1952, the matter was jointly considered and approved by the Presbyterian and Methodist missions He came back to stay in June, two years later, under the auspices of the newly formed United Mission to Nepal

'I had some small equipment I brought up with me," he recollected for us "I ordered some other supplies and some medications, and while that was in the process of coming (it takes things three months to get here) I had a little bit of stuff—plus a microscope or two—to get started with"

'What did you do to start?'

"I collected some boys, the equivalent of our high school students, and a compounder, who corresponds somewhat to our pharmacist at home, and began training them in the basic sciences and in rudimentary nursing procedures, including training in laboratory techniques and public health Later on my first missionary nurse came and took over the training in nursing We opened for business the first of September, 1954"

Hospital and home for Dr Friedericks was a rented building—"the biggest building in town with water on tap'—with which he was making do until a new hospital he was building of adobe brick was completed His practice?

"Routine clinical practice plus some surgery I've taught my compounder how to give anesthesia"

The people had practically no experience with modern medical practice until the doctor arrived—especially surgery From Gorakhpur in northern India, 80 miles away, to Tibet and beyond (who knows?) there was no modern hospital service available to them before

His patients represent a cross section of the community Magars, village folk, Newars, early town settlers, Gurungs, Gurkhas, the warrior class, Brahmins, the highest caste, and occasional Tibetans They are extremely conservative, and the later arrival of an English lady physician, Marjorie Foyle, helped considerably in treating the female patients (When we were there, Dr Foyle was in India on leave)

We asked the doctor what diseases seemed most common in his area

"Our major problem, as in most of Asia, consists of infectious diseases of all kinds We have widespread cases of amebic dysentery Tuberculosis is another serious problem—all kinds of tuberculosis We get malaria cases from the valley below, but rarely from our immediate region We also see cases of roundworms and hookworms and other intestinal parasites a lot of general infection of wounds, that become infected due to neglect and the usual injuries—people kicked by horses, or falling from trees, etc"

'Surgery?'

'Bladder stones are very common Intestinal obstructions, sometimes Quite a bit of bone surgery And skin graft work, too since they commonly build fires on the floor and let the children play close by unattended But I've had only one appendix case since I've been here!'

He took us down and showed us the hospital itself It was a 10-bed hospital occupying the first-floor area ist below the doctor's living quarters Its appointits were very primitive It was strictly a case of e-do, the best one can until the new hospital is ready Empty oil tins served as bedstands Rough wooden frames, webbed, formed the beds Lights were kerosene lamps, when they needed to be pressed into service, for every drop of oil was precious, having to be carried by foot over the same mountains and plains we had traveled He was proudest of his x-ray machine, and the gasoline-operated generator he turned on when he wanted to use it We saw the following patients A very badly burned man who had run into a blazing house to save his goods, a severe case of hookworm and tuberculosis of the bone, combined, a case of severe dysentery, a boy of about 10 who had broken his arm in a fall, and a case of Kala-azar "black fever'—a parasite disease, carried by the sandfly, in which the spleen and liver are affected and become enlarged

Later I accompanied the doctor on a house visit, which he makes rarely for lack of time We found a member of the family waiting for us outside the door We saluted him by placing the palms of our hands together and raising them to our face, and entered, mounting a flight of stairs

"This family is comparatively well-to do,' explained the doctor as we went up We took off our shoes at the open entrance of the room and went in The patient, an elderly woman, was lying on a mat on the floor There was no furniture about The doctor squatted down, and after hearing from patient and family, examined the mother

"There's an obstruction of the urethra," he said "I'll have to have her over to the hospital to do any good

He made this clear to the patient and the assembly, and as we prepared to leave they brought in a younger woman who had had a tooth removed The doctor soon learned that she had apparently been given penicillin to which she had had a reaction The doctor advised her to stop taking the penicillin and we took our leave

As we turned down the cobbled street toward home, the doctor said

'They know about penicillin and streptomycin They've found out about them somehow We do get a few wandering drug sellers up this way But what they don't know is how to use them properly They don't know that improperly prescribed, they can often be harmful instead of helpful'

We spent about four days in Tansen, seeing not a single wheeled vehicle of any kind the whole time we were there We filmed the doctor as he treated his hospital patients, left the hospital to visit a nearby public school for his annual examination of the children, and, finally, with the arrival of long-awaited supplies, followed him out to a native village in the cholera area to inject the population for protection

If I can prevent one year's outbreak of cholera in one village, he said, "then I've really accomplished something'

Thus, for the "March of Medicine's' hour-long television report on American doctors the world over, we will bring back the story of perhaps the most remote of our American doctors—a man whose trail can be followed through the birthplaces of his family He himself was born in Germany, his wife in Korea

"Richard was born in Reading, Pa , Charles in India, and James, our youngest, in Nepal James, as far as we know, is the first American to be born in Nepal"

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Incidence of Chronic Pulmonary Disease Among Patients with Esophageal Disorders J R Vivas and E D Palmer Dis Chest 31 568 574 (May) 1957 [Chicago]

Chronic pulmonary disease is a threat in patients who have an esophageal lesion that causes esophageal retention or transcardial reflux The conditions arousing most interest in this respect are achalasia, diverticulosis, chalasia, hiatus hernia, esophageal foreign body, and stricture Pulmonary involvement seems to result from periodic unrecognized aspiration of material from the esophagus Presumably, this is largely a nocturnal affair, or at least recumbency favors migration of esophageal contents The severity of pulmonary disease encountered in some instances of achalasia and of esophageal diverticulosis has been disturbing, and more information is needed on the incidence of both clinical and subclinical pulmonary disease in all esophageal abnormalities, both those of a retentive nature and those causing dyskinetic effects The records of inpatients discharged from the Walter Reed Army Hospital during the calendar year of 1954 with diagnoses which included an esophageal disease were reviewed, but those with esophageal varices only were not included There were 68 in this series In order to include patients whose illness was not serious enough to require hospitalization, 32 additional outpatient records were selected at random to bring the total number to 100

The group included 65 males and 35 females, ranging in age from 12 months to 89 years Chronic pulmonary disease was found in 22 patients, that is, in 2 of 42 patients with hiatus hernia without secondary esophageal change, in 4 of 13 with diverticulum of the esophagus, in 2 of 12 with subacute erosive esophagitis without hiatus hernia, in 6 of 8 with achalasia, in 3 of 7 with subacute erosive esophagitis with hiatus hernia, in 2 of 3 with carcinoma of the esophagus, in 1 of 3 with Zenker's diverticulum, and, whereas both of the patients with esophageal stricture due to swallowing lye had chronic pulmonary disease, none of the 10 patients with other forms of esophageal strictures showed pulmonary involvement These 10 included 6 with stricture secondary to esophagitis, 3 with congenital stricture, and 1 with radiation stricture This study was undertaken not to prove cause and effect relationship but to bring out the high incidence of transadital aspiration type of pneumonitis in esophageal disease

Experience with Anticoagulant Treatment V Debenedetti and M Ravera Minerva med 48 1160-1165 (April 7) 1957 (In Italian) [Turin, Italy]

The authors report on the results of anticoagulant therapy in 390 patients treated for a total of 11,469 days Eighty-seven patients had myocardial infarction, 131, phlebitis and thrombosis, 27, cerebral thrombosis, 41, pulmonary embolism, 19, coronary insufficiency, 48, cardiopathies with decompensation, and 37, arteritis The treatment was always started with heparin and continued with Dicumarol The best results were obtained in patients with phlebitis and phlebothrombosis, pulmonary embolism, myocardial infarction, and in many patients with heart failure The authors used Quick's test for the control of the prothrombin level Severe hemorrhage can be avoided if the test is used regularly and on fresh samples of blood Severe hemorrhage occurred in 3 patients but was checked by suspension of the administration of the anticoagulant and with intravenous injections of vitamin K_1 Thirty-six minor hemorrhages were checked by diminishing the dose of the anticoagulant There is no risk in a well-controlled treatment Anticoagulant therapy is indicated for the prevention and treatment of postoperative complications which are mainly of a thromboembolic nature

Preliminary Report on Long Term Treatment of Cardiosclerosis with Dicumarol K K Bengtsen and G Aspenstrom Acta med scandinav 157 217-222 (No 3) 1957 (In English) [Stockholm]

Dicumarol was given to 82 selected patients with myocardial infarction and to those with angina pectoris for an average time of 14 5 months Severe cases and poor-risk patients were relatively numerous No thromboembolic complications occurred in the 62 patients who are still receiving treatment The death rate due to cardiac disease was 9 8% within the first year and 7% during the second and third years of treatment with Dicumarol, whereas the death rate of untreated patients with myocardial infarct or angina pectoris appeared to be 15 to 18% within the first year after diagnosis and about 9% during the following 2 years Treatment was discontinued in 12 patients One died from cerebral embolism and 4 had various thrombotic complications It is suggested that these complications were due to the sudden withdrawal of the drug Of 72 patients with angina pectoris 46 felt improvement, but this cannot with any certainty be ascribed to the anticoagulant Hemorrhagic complications were rare and easy to control For long-term therapy smaller doses of Dicumarol might be effective Differentiation between good-risk and poor-risk patients should be made The patients classified ' stress

The place of publication of the periodicals appears in brackets preceding each abstract

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals Requests for periodicals should be addressed Library, American Medical Association Periodical files cover 1948 to date only, and no photoduplication services are available No charge is made to members, but the fee for others is 15 cents in stamps for each item Only three periodicals may be borrowed at one time, and they must not be kept longer than five days Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them hyperreactors' with regard to the coagulability of their blood will benefit the most from treatment with Dicumarol Prolonged anticoagulant therapy does not yet incontestedly appear to be superior to other therapy for some types of cardiovascular disease

The Arterial Hypertension of Chronic Mercury Poisoning F Gobbato, G Scansetti and F Capellaro Minerva med 48 1209-1216 (April 11) 1957 (In Italian) [Turin, Italy]

The relation between prolonged occupational exposure to mercury and various cardiovascular-renal findings was investigated in 28 workmen Their ages ranged from 26 to 67 years, and the periods of exposure from 6 to 45 years, all manifested some degree of chronic mercurialism and were receiving compensation for disabilities ranging from 21 to 100% of their normal working capacity Within this limited group the systolic blood pressure was found to increase much faster (2 42 mm Hg per year) after age 40 than it does in the general population (0 433 mm Hg per year) The same was true for the diastolic pressure Statistically significant positive correlations were found *(a)* between systolic blood pressure and duration of exposure to mercury and *(b)* between diastolic pressure and severity of symptoms of intoxication Data on the velocity of the pulse wave in the aorta, on cardiac output, on renal blood flow, and on urea clearance were obtained in 12 subjects, and electrocardiograms from 15 have been analyzed in detail From these and other data it is concluded that alterations of renal function directly attributable to chronic mercurialism are infrequent and that when renal alterations do occur they are probably the usual local effects of a general arteriosclerosis The hypertension can be explained as originating in the central nervous system The organic lesions known to occur in the nervous system can involve the central mechanism that regulates blood pressure, and they suffice to explain the neurological, emotional, and vascular phenomena of chronic mercurialism

Effects of Aldosterone on Water, Electrolyte, and Nitrogen Metabolism in Addison's Disease R M Salassa, H L Mason, V R Mattox and others Proc Staff Meet Mayo Clin 32 201-212 (May 1) 1957 [Rochester, Minn]

Aldosterone has been isolated, structurally identified, and synthesized in the last several years This potent sodium-retaining steroid has been found in adrenal and systemic venous blood and in the urine Studies not only indicate that aldosterone is more potent than desoxycorticosterone acetate in causing sodium retention and potassium excretion but also suggest that there are other significant differences Whereas earlier work with aldosterone suggested that the administration of this steroid would not result in edema and excessive retention of sodium, later reports indicated that in doses of about 1 mg per day for 6 days aldosterone would cause retention of salt and water with mild edema and increase of intracellular fluid The authors gave aldosterone to 3 patients who had adrenocortical hypofunction and observed the effects of moderate and relatively large doses of the steroid on electrolyte and nitrogen balance, total body water, exchangeable sodium, and blood electrolytes They found that aldosterone is capable of correcting the electrolyte and water imbalances associated with Addisonian crisis and of maintaining electrolyte balance in patients who have adrenocortical hypofunction The daily intramuscular administration of 400 or 800 mcg of aldosterone for 7 to 14 days resulted in increased exchangeable sodium, increase of total body water, increase of extracellular fluid space, and development of mild edema No hypertension, alkalosis, or change in pigmentation was observed during the administration of aldosterone, and there was no significant change in nitrogen balance These studies indicate, as do previous observations by others, that large quantities of aldosterone are needed before one can produce and study the full picture of hyperaldosteronism in man

Thalassemia Minor Experience with 50 Consecutive Patients M B Burris and R Barzilai J Florida M A 43 1204-1206 (June) 1957 [Jacksonville]

The authors report on 50 patients with thalassemia minor referred to the section on hematology at the Ochsner Clinic in New Orleans Nine of the patients were of Anglo-Saxon, 3 of French, 30 of Italian, 4 of Spanish, and 4 of Greek descent Most of the patients were from the southern states Only 10 had a hemoglobin level of less than 9 5 Gm per 100 cc In most of the patients the hemoglobin level ranged from 10 to 13 5 Gm per 100 cc The red blood cell count ranged from 3,200,000 to 7,000,000 per cubic millimeter Reticulocytes were elevated above 2% in 19 patients, the highest count being 7% The bilirubin level was elevated in only 2 of the 10 patients in whom it was determined The degree of anisocytosis, poikilocytosis, and microcytosis was variable and did not correlate well with the level of hemoglobin Patients with symptoms attributed to anemia frequently had these symptoms first on reaching some period of emotional stress well after maturity In many the symptoms first appeared after anemia had been recognized and the patient had undergone a prolonged period of futile treatment Thirty-four patients had been treated for periods up to 10 years with iron, vitamins, cobalt, and liver with or without other indications Although such treatment is not physically harmful, with the possible exception of excessive iron or cobalt, those who were treated most energetically had the most severe functional complaints There were no positive physical findings other than a variable degree of pallor and a palpable spleen in 13 of the 50 patients

Thalassemia minor is frequently overlooked as a cause of microcytic anemia Characteristically the mean corpuscular volume is low, the mean corpuscular hemoglobin decreased, and the mean corpuscular hemoglobin concentration normal or slightly below There is increased resistance to hypotonic sodium chloride solution Reticulocytes are normal or moderately increased Indirect bilirubin is normal or moderately increased The bone marrow shows an increase in normoblasts The serum iron level is elevated and the iron-binding protein is saturated Of great diagnostic significance are similar hematological findings in one of the parents The disease is not infrequent among the Mediterranean races, is seen occasionally in patients of other racial extraction, and is not rare in the southern part of the United States The diagnosis is not difficult to make once the condition is considered Before their admission to the hematological department, anemia had been previously recognized in 39 of the 50 patients, although the diagnosis of thalassemia minor had been considered in only 4 Ordinarily the anemia causes no symptoms or only mild complaints Unrelated functional complaints are common

Treatment of Lupus Erythematosus with Antimalarial Drugs M H Foss Tidsskr norske lægefor 77 341-344 (April 15) 1957 (In Norwegian) [Oslo]

During the last several years, Resochin therapy has been the standard method of treatment applied in the Rikshospital in the chronic discoid form of lupus erythematosus The substance was usually given in doses of 0 25 Gm twice daily for a week, then 0 25 Gm daily The treatment lasted for from 1 week to 22 months, average time 16 weeks Follow-up of 57 patients (19 men, 38 women), aged between 30 and 60, with chronic discoid lupus erythematosus treated in the dermatologic department of the hospital in 1955 showed a complete regression in 20 cases, in 14 of which subsequent relapse occurred, improvement in 24, no response in 12, and aggravation in 1 case Side-effects were seen in 21 cases The treatment had to be discontinued in 9 cases but could be resumed in 4 Great caution is called for in the use of Resochin in treatment of systemic lupus erythematosus, if it is applied in such cases, combined treatment with cortisone is advised

Technic of Controlled Drug Assay Illustrated by a Comparative Study of Rauwolfia Serpentina, Phenobarbital and Placebo in the Hypertensive Patient A P Shapiro and H C Teng New England J Med 256 970 975 (May 23) 1957 [Boston]

A technique for controlled drug assay applied to a comparison of Rauwolfia serpentina and phenobarbital in a group of 144 ambulatory patients with mild to moderately severe hypertension is described The patients were divided at random into 3 groups of 48 each and given alseroxylon (Rauwiloid), phenobarbital, and placebo respectively Most of the patients were told that a new medicament was being given them, but they were not informed of its nature The physicians in the clinic had no knowledge of which preparation a given patient was taking The patients were not assigned to any one physician in the clinic, to ensure randomization study of the effect of the doctor-patient relation Psychotherapeutic measures were avoided as much as possible Sixteen patients did not return to the clinic after the initial visit The average duration of treatment was approximately 30 weeks, identical for each group In 1 patient receiving Rauwiloid a subarachnoid hemorrhage developed, and he died Improvement in over-all function was noted in about a third of the patients receiving placebo and Rauwiloid and in more than a half in the group given phenobarbital However, there was no difference in effects on headache and cardiovascular symptoms Side-effects were found in 30% of the patients given placebo, in 62% of those given Rauwiloid, and in 43% of those receiving phenobarbital Rauwolfia alkaloids produce a slight but definite decrease in peripheral resistance The tendency to weight gain, evoked by the Rauwolfia alkaloids, and their production of various troublesome side effects may outweigh the hypothetical benefits derived from their quite modest effect on peripheral resistance Phenobarbital sedation is capable of decreasing blood pressure to a lesser degree but with less intense side effects, no weight gain, and a more intense feeling of well-being in the hypertensive patient The experimental design employed in this study is recommended for use in similar drug assays

Spontaneously Regressive Enlarged Mediastinal Lymph Nodes in the Adult On the Basis of 12 Cases J Lemenager, J Porin and J Rousselot Semaine hôp Paris 33 1526-1535 (April 20) 1957 (In French) [Paris]

The increasing use of routine radiologic examinations has led, in recent years, to the discovery in many persons, usually anergic to tuberculin, of enlarged mediastinal lymph nodes that cause no symptoms and that regress spontaneously after periods varying from a few weeks to a few months The benign nature of the enlargement cannot be immediately affirmed, because Brill-Symmers disease in its initial phase may be characterized by a mediastinal lymph-node tumor that later becomes secondarily malignant The follow-up in an appreciable number of cases, however, has been long enough to justify the recognition of a group of benign conditions of the mediastinal lymph nodes that progress spontaneously and definitively to cure The origin of these conditions has not yet been determined, but 3 principal causes have been suggested bacterial or viral infection, tuberculosis, and Besnier-Boeck-Schaumann sarcoidosis

Tests designed to reveal the presence of infection usually produce negative results, although it has been possible in a few instances to identify a specific virus Thus ornithosis was discovered in one patient, another had infectious mononucleosis, and in others cat-scratch fever and benign postvaccinal lymphoreticulosis were demonstrably present The infrequency, however, with which proof of viral infection can be obtained in patients with apparently benign mediastinal lymph-node enlargement has led investigators to turn their attention chiefly to tuberculosis and Besnier-Boeck-Schaumann sarcoidosis as possible causes of the enlargement The tuberculin anergy usually found in the patients is not incompatible with the presence of tuberculosis, because tuberculin-induced reactions are sometimes very slight and inconstant even in patients with genuine tuberculosis The discovery of lymph-node or pulmonary tuberculosis does not exclude the possibility of sarcoidosis, since the two conditions may coexist Several workers have suggested that the enlarged lymph nodes are in reality purely mediastinal forms of Besnier-Boeck-Schaumann sarcoidosis and that the polyvisceral character of the disease will become evident later on in other parts of the body The possibility that sarcoidosis may be present in these patients should be kept in mind, but, because of the frequency with which spontaneous regression of the enlarged lymph nodes takes place and because of the apparently benign nature of the condition, even when the enlargement shown by the x-ray examination is striking, a diagnosis of sarcoidosis or tuberculosis should not be made without adequate histological or bacteriological proof Similarly, the mere fact that the mediastinal lymph nodes are enlarged should not be regarded as justifying immediate x-ray treatment

Diagnostic Difficulties During the Simultaneous Occurrence of Tuberculosis and Bronchogenic Carcinoma T A J Kroon, J G Roosenburg and H Deenstra Nederl tijdschr geneesk 101 822-824 (May 4) 1957 (In Dutch) [Haarlem, Netherlands]

The histories of 5 patients are presented that demonstrate the difficulty of detecting a bronchogenic carcinoma in a patient with pulmonary tuberculosis The authors emphasize that the possibility of the simultaneous existence of a pulmonary carcinoma should be considered in all patients with pulmonary tuberculosis who are over 40 An unusual course of tuberculosis, an enlarging focus, the development of an obstructing infiltration, or the fact that there are not many tubercle bacilli demonstrable in the presence of a cavity should raise the suspicion of the presence of a pulmonary carcinoma

The Vascular Complications of Diabetes Mellitus A Clinical Study J W Bryfogle and R F Bradley Diabetes 6 159-167 (March-April) 1957 [New York]

Vascular disease has increased in importance in patients with diabetes mellitus since the introduction of insulin has reduced the incidence of coma and infection as causes of death and thereby increased the life expectancy The authors investigated 394 diabetic patients, selected regardless of age or duration of diabetes for the presence of 4 vascular complications diabetic retinopathy, diabetic nephropathy, peripheral vascular disease, and arteriosclerotic heart disease At least one of these vascular lesions was found in 49 5% (195 patients) In almost one-half of these, more than one type of vascular complication existed After 20 or more years of diabetes, 87 5% of these patients had one or more vascular complications Retinopathy was most frequently seen, being present in over 50% of those with diabetes for 10 to 15 years and in more than 84% of those with diabetes for 20 years or longer Diabetic nephropathy was present in approximately 10% of all patients and in 24% of those with diabetes for 15 years or more Peripheral vascular disease was noted in 15 7% of these diabetics Arteriosclerotic heart disease was present in 18 5% of the entire series and in 26 5% of those beyond age 39 Angina pectoris and myocardial infarction were present in 12 3 and 11 3%, respectively, of patients over the age of 39 When more liberal criteria were used, the likely incidence of arteriosclerotic heart disease was 56 2% at age 40 or more and for those aged at least 50, 66 4% The most characteristic diabetic vascular lesions, retinopathy and nephropathy, were related chiefly to the duration of diabetes Arteriosclerotic heart disease and peripheral vascular disease, which are less specific for diabetes, were related in their incidence both to the age of the patient and to duration of diabetes

Epidemic Rheumatic Fever Problems in Control at a Recruit Training Base B M Reen, N Schalet and H B Houser U S Armed Forces M J 8 802-810 (June) 1957 [Washington, D C]

The exact nature of the relationship between group A streptococcic infections and rheumatic fever has not been established It has been shown that first attacks of rheumatic fever can be prevented by adequate treatment of streptococcic infections with penicillin or broad-spectrum antibiotics In the general population this is difficult, and, while it has been suggested that the "captive population" of a military base would be an ideal group in which to treat acute streptococcic infections for prevention of rheumatic fever, this article outlines some of the difficulties in such a program and the specific measures employed to reduce the incidence of rheumatic fever A throat culture was obtained from all patients with respiratory disease admitted to the base hospital at Sampson Air Force Base in New York state Strains of beta-hemolytic streptococci isolated from these cultures were identified by Lancefield group and type The hospital charts of all patients with a discharge diagnosis of acute rheumatic fever were reviewed The hospital admission rate of patients exhibiting 10 or more colonies of group A streptococci on admission throat culture is shown in a graph The predominant type of group A Streptococcus throughout the study period was 19 The admission rate of streptococcic pharyngitis rose rapidly during the late fall months to a peak of 12 5 cases per week per 1,000 men, dropped in late December, coincident to the Christmas and New Year's leave period, and then rose rapidly to a peak of 11 3 by Jan 26 At this point, penicillin prophylaxis was administered on a base-wide scale, and the rate dropped off precipitously The rate began to rise again in the early weeks of March and reached a peak of 12 7 by early April This rate was sustained until mid-June and thereafter fell off to negligible levels for the summer

The rate of rheumatic fever rose with the increased hospital admissions for streptococcic disease and fell off at the time of penicillin prophylaxis Two weeks after the streptococcic infection rate again began to rise, the incidence of rheumatic fever began to increase Although the streptococcic hospitalization rate again reached proportions similar to those earlier in the season, the concomitant rise in rheumatic fever was less than earlier Several possible explanations for the failure of the rheumatic fever rate to parallel the streptococcic infection rate in the second half of the reporting period are discussed Host susceptibility seems likely Some families have a higher rheumatic fever incidence, and the tendency of rheumatic fever subjects to have recurrences is recognized The seasonal variation in the incidence of rheumatic fever merely reflects the seasonal incidence of streptococcic infections The presence of a particularly virulent rheumatogenic strain of Streptococcus in the early part of the winter seems unlikely in view of the fact that there was no type change in the streptococci responsible for disease during the 2 periods

A graph indicates that during the weeks prior to penicillin prophylaxis many cases of streptococcic infections were either not recognized or inadequately treated Little more than 25% of the estimated cases of streptococcic disease reached the hospital, whereas after the period of penicillin prophylaxis over 50% of the estimated patients were hospitalized and adequately treated It is difficult to make the trainee return for further penicillin therapy after his symptoms have subsided, and it is advisable to treat persons with streptococcic pharyngitis in the hospital By hospitalization of patients with respiratory disease many cases of streptococcic infection that would otherwise have gone unrecognized were discovered and treated

Rheumatic Manifestations in Hodgkin's Disease, Leukemia and Allied Conditions E Paguet and J-M Delage Canad M A J 76 927-933 (June 1) 1957 [Toronto, Canada]

The authors report the occurrence of rheumatic pain in 24 of 108 patients with Hodgkin's disease, in 6 of 43 patients with acute leukemia in 2 of 13 patients with lymphosarcoma, in 1 of 36 with chronic lymphocytic leukemia, in 4 of 19 with granulocytic (myelocytic) leukemia and in 6 of 15 with plasma cell (multiple) myeloma The spine was most commonly involved in patients with Hodgkin's disease, the lumbar or thoracolumbar segments were the most commonly affected and next, in order of frequentcy, the sciatic area or legs and the hip joints Symptoms referable to the bone and joints were more frequently seen in children with acute leukemia than in the other types of leukemia Diagnostic difficulty may exist with rheumatic fever The pain occurred usually at the onset of the disease in patients with acute leukemia and multiple myeloma but more often in the course of the disease in patients with Hodgkin's disease No constant relationship existed between painful manifestations and x-ray patterns Although infrequent in chronic leukemia, rheumatic pain was more often observed in granulocytic than in lymphocytic types

Blood Ammonia Levels in Hepatic Cirrhosis Their Control by the Oral Administration of Neomycin C J Fisher and W W Faloon New England J Med 256 1030-1035 (May 30) 1957 [Boston]

The relation between elevated blood ammonia concentrations and the development of hepatic coma has called attention to the production of ammonia by bacterial enzymatic action upon urea and other nitrogenous compounds in the gastrointestinal tract This has led several authors to suggest that antibacterial agents effective against intestinal organisms might be beneficial in this type of coma This communication reports the effect of oral administration of neomycin upon blood "ammonia" concentrations and upon mental status in patients with cirrhosis To elucidate the mechanism of the effects observed, observations upon fecal bacterial flora and upon ammonia concentration in arterial, peripheral venous, abdominal collateral, and portal vein blood also were carried out

It was found that administration of neomycin orally in doses of 8 to 12 Gm daily reduced venous blood ammonia to normal levels in 12 studies in 11 patients, 2 of whom were examined in 4 episodes of stupor or impending hepatic coma Clinical improvement was observed in the patients with neurological or mental symptoms After withdrawal of neomycin in 8 patients without neurological changes, the blood ammonia level rose promptly to control levels in 7 and showed a delayed rise in the 8th patient Stool cultures obtained during neomycin administration either were sterile or revealed urease-negative organisms regardless of the dose received Neomycin was found in the blood in insignificant concentrations except in the presence of renal disease with nitrogen retention It is concluded that neomycin reduces the blood ammonia level in patients with cirrhosis, with or without neurological changes, by virtue of its effect upon the bacterial flora of the intestine Neomycin is an effective therapeutic agent in patients with hepatic cirrhosis and ammonia intoxication

Hepatic Coma A Clinical Study M Delp, W G Calkins and R W Weber Arizona Med 14 335-342 (June) 1957 [Phoenix]

The authors report on 43 patients, 21 male and 22 female, between the ages of 8 and 75 years, with liver disease manifesting coma Irritability, confusion, lethargy, flapping tremor, and fetor hepaticus formed the most helpful symptoms and signs in predicting that coma was imminent Biochemical liver-function tests were not helpful in predicting the onset of coma Although it is commonly stated that patients in hepatic coma have hypoglycemia, this was not observed in any of the 43 patients A factor precipitating hepatic coma was strongly indicated in 39 patients Of these, 21 had evidence of gastrointestinal bleeding with blood in the intestinal tract before the onset of coma Three patients had received ammonium chloride before the appearance of coma One patient had received amino acid preparations intravenously One had received exchange resins containing ammonium Thus 26 patients had unusual amounts of nitrogenous substances in the intestinal tract before coma developed Pneumonia occurred before the onset of hepatic coma in 3 patients Precoma and coma rapidly followed paracentesis in 3 patients Coma occurred after surgical intervention in 2 patients Coma followed the administration of barbiturates in 2, of narcotics in 1, and of acetazolamide in another An alcoholic debauch immediately preceded hepatic coma in only 1 patient

Although the exact mechanism is not clear, more and more evidence is accumulating to indicate that increased blood ammonia levels are important in the causation of hepatic coma Blood ammonia concentrations were determined in 100 normal blood donors Values between 50 and 110 mcg per 100 cc were considered normal Values between 111 and 135 mcg per 100 cc were considered to be borderline, and values over 135 mcg per 100 cc were considered definitely abnormal Blood ammonia levels were determined in 14 patients with liver disease, 8 with hepatic coma and 6 without Of the 8 patients, 3 had normal blood ammonia levels and 5 had abnormally high blood ammonia levels on at least one occasion All 6 patients without coma had normal ammonia levels

A Study of the Relation of the ABO Blood Groups to Peptic Ulceration and Hypertension S Pell, C A DAlonzo and A J Fleming Ann Int Med 46 1024-1030 (June) 1957 [Lancaster, Pa]

Reports in the literature on significant relationship between ABO blood groups and certain diseases induced the authors to study the distribution of blood groups in 12,904 employees of the DuPont Company whose blood types were available Among the various diseases prevalent in this population, peptic ulcer and hypertension were the only 2 the incidence of which was high enough for adequate statistical analysis The study of the distribution of blood groups in 298 persons with a history of peptic ulcer showed an increased frequency of O blood and a reduced frequency of A blood of about 5% when compared with a control group of employees without history or evidence of peptic ulcer This relationship is consistent with, but not so great as, that observed by other investigators The findings concerning the distribution of blood groups in 508 persons with hypertension were inconclusive but did suggest that there may be a slightly greater chance of the possible occurrence of hypertension in persons with type A blood than in those with type O blood Additional data are needed to clarify the nature and extent of this relationship Consideration might be given to these findings in a preventive medical program

SURGERY

Intracardiac Surgery in Deep Induced Hypothermia H B Wulff, K Hæger, H Ryd and others Acta chir scandinav 112 186-198 (No 3-4) 1957 (In English) [Stockholm]

Nine children, 5 girls and 4 boys, between the ages of 2½ and 14 years and 1 22-year-old woman with congenital heart disease were operated on while under hypothermia Eight patients had atrial septal defects, 1 had tetralogy of Fallot, and 1 had transposition of the aorta and valvular pulmonary stenosis The patient was given premedication on the day of the operation with 1 mg of chlorpromazine, 0 5 mg of meperidine (Demerol) hydrochloride, and 0 01 mg of atropine per kilogram of body weight Anesthesia was induced with vinyl ether–ether, after which an endotracheal tube was introduced A heart catheter was passed by way of the saphenous vein until its tip lay roughly at the level of the diaphragm Through this catheter the patient received 1 mg of procaine amide per cubic centimeter of dextran solution by drip The drop rate was adjusted so that from 500 to 1,000 cc of the solution was infused during the cooling procedure In addition, the patient was given 100 mg of procaine amide at the beginning of the operation and another 100 mg shortly before the circulation was shut off Highly cold-sensitive parts of the body, such as the hands, feet, ears, and external genitals, were wrapped in cotton wool, and a few drops of liquid paraffine were inserted into the eyes, after which the nude patient was enclosed in a thermobox in which hypothermia was induced by circulating cold air The cooling procedure required between 1 3 and 2 5 hours according to the body surface and weight of the patient At from 28 to 30 C (82 4 to 86 F) deep rectal temperature, the patient was removed from the box and the operation was started The temperature decreased regularly 2 or 3 degrees after removal of the patient from the box During the initial phase of the cooling procedure, the patient spontaneously breathed a mixture of oxygen, nitrous oxide, and ether in a semiclosed system with carbon dioxide absorption At 33 C (91 4 F) respiration was taken over by the anesthetist, whether spontaneous respiration was satisfactory or not Vigorous hyperventilation was started, with 30 to 40 respirations per minute Any tendency to shivering was controlled by intravenous injection of minimal doses of succinyl choline (10 to 20 mg) or chlorpromazine (10 to 25 mg) The patient was rewarmed after the operation in the box with warm circulating air (45 C [113 F]) Rewarming usually required 2 to 4 hours

Nine of 10 patients operated on while under hypothermia survived the hypothermia and the operation One died in the course of the operation Autopsy revealed not only a larger atrial defect than that for which he was operated on but also a ventricular septal defect Surgery and not hypothermia must have been responsible for his death Septicemia caused the death of a second patient on the 18th postoperative day Autopsy revealed a trilocular heart with atrophy of the right ventricle but normal tricuspid valves emptying into the left ventricle The septicemia was explained by suppurative endocarditis Whether or not hypothermia as such contributed to the development of septicemia is difficult to say Cardiac standstill occurred in 1 patient when the thorax was opened The complication was immediately detected, thanks to cardioscopic control, and successful cardiac massage was started within 1 minute It is probable that the cardiac standstill was at least partly precipitated by the injection of 100 mg of procaine amide into the inferior vena cava Since then this drug was injected over a longer period and the commercial solution was diluted 1 10 with isotonic sodium chloride solution Six of the patients operated on had a slight rise of temperature postoperatively for periods up to 3 weeks The immediate risks of surgical treatment during hypothermia may be somewhat greater than during normothermia, but the bloodless heart permits much more radical intervention and better late results

Effect of Bilateral Adrenalectomy on Diabetes Mellitus H J Wolff, B J Kennedy and M B Johnson Minnesota Med 40 318-321 (May) 1957 [St Paul]

The authors comment on the relentlessly progressive vascular disease seen in some patients with diabetes mellitus, pointing out that juvenile diabetic patients are especially prone to have premature arteriolar degeneration, with vascular lesions making their first appearance from 5 to 15 years after the onset of clinical diabetes Microaneurysms in the retinal arterioles are often recognized in the early stages of vascular degeneration, and the kidney frequently follows as a major area of impact Kimmelstiel and Wilson observed in diabetic persons intercapillary glomerulosclerosis characterized in the advanced stages by hypertension, retinitis, nitrogen retention proteinuria, and hypercholesterolemia with eventual renal failure and death Hypoglycemic and hyperglycemic stress factors and resultant adrenal cortical dysfunction are readily recognized in the clinical course of most patients with diabetes in whom early vascular degeneration is prone to develop and this suggested that total bilateral adrenalectomy might modify the arteriolar degenerative lesions of diabetic patients

The authors review the literature on adrenalectomy in diabetes mellitus and report the history of another young diabetic patient with associated vascular disease who underwent total bilateral adrenalectomy At least 12 diabetic patients have been reported on in whom bilateral adrenalectomy was carried out because of advanced vascular disease Five of these 12 died postoperatively due to either adrenal insufficiency (3) or continued progression of the degenerative vascular lesions (2) It appears that at least one reason for the unfavorable outcome of adrenalectomy lies in the advanced degree of vascular deterioration that has always been present before operation was considered Several authors advocated that patients with evidence of severe vascular and renal deterioration, significant nitrogen retention, proteinuria in excess of 5 Gm daily, and diastolic blood pressures more than 120 mm Hg should be excluded as candidates for adrenalectomy Total bilateral adrenalectomy as a therapeutic measure in the initial stages of arteriolar degeneration would appear to represent radical therapy, but it is evident that procrastination until the vascular or renal lesions have reached the stage of irreversibility has not been successful As an ancillary procedure calculated to prolong life in a diabetic patient with advanced vascular disease, total adrenalectomy does not appear to deserve approbation

Wedge Resection in the Treatment of Tuberculosis A Study of 150 Operations J J Quinlan, V D Schaffner and J E Hiltz Canad M A J 75 842-844 (May 15) 1957 [Toronto, Canada]

It has been widely accepted for a number of years that closed caseous tuberculous lesions that remain after the completion of other types of therapy should be resected At the Nova Scotia Sanatorium, a large proportion of such lesions were found to be located near the periphery of the lung and so could be removed by a simple wedge resection The sanatorium records of 144 patients who underwent 150 consecutive wedge resections between September, 1951, and September, 1955, were reviewed The closed caseous lesions remained after prolonged therapy with a combination of at least 2 tuberculostatic agents The chest was entered through the 4th and 5th intercostal space by a posterolateral thoracotomy There was 1 postoperative death, in a 52-year-old man, which seemed to have been caused by coronary occlusion No complications resulted in 131 (87 3%) of the operations So-called stubborn space, a pleural space that was still present 2 weeks after the operation, was the most frequent complication, occurring after 13 of the operations All but one of these spaces eventually became obliterated There were 3 empyemas, 2 tuberculous and 1 nontuberculous All resolved with needle aspiration and antimicrobial therapy In 3 instances, tuberculous disease may have spread Bronchopleural fistula and wound infection occurred in 1 patient each Bacteriologic examination of the resected specimens revealed tubercle bacilli in 58 on either slides or cultures The authors conclude that the results of wedge resection are generally very satisfactory

Clinical Studies in Extracorporeal Circulation with a Heart-Lung Machine C Crafoord, B Norberg and A Senning Acta chir scandinav 112 220-245 (No 3-4) 1957 (In English) [Stockholm]

Intracardiac operations were performed with the aid of extracorporeal circulation using a specially devised heart-lung machine in 5 children between the ages of 2 and 15 years and in 8 adults between the ages of 17 and 52 years with congenital and acquired heart disease The heart-lung machine consisted of an oxygenator and a pumping device combined with a regulating unit The artificial oxygenation took place by means of rotating screen cylinders, and the effect could be raised with a preoxygenator of the bubble type Venous return to the machine was accomplished by gravity, and no attempt was made to restrict the flow The artificial heart consisted of an automatically regulated pump The heart-lung machine was filled with freshly-drawn heparinized blood from donors Of the 13 patients, 1 had an aneurysm of the left ventricle, 2 had ventricular septal defects, 3, atrial septal defects, 1, combined atrial and ventricular septal defects, 2, congenital aortic stenosis, 1, complete transposition of the great vessels, 1, isolated infundibular pulmonary stenosis, 1, mitral stenosis, aortic stenosis and tricuspid insufficiency, and 1 ventricular septal defect and valvular pulmonary stenosis

Five of the 13 patients died, in 1 of the 5, death was caused by an error in the procedure, since the flow rate of perfusion was too low during a considerable part of the intracardiac operation One 2-year-old girl died within 24 hours after the operation, and no satisfactory explanation of the cause of death was found The death of the patient with transposition of the great vessels resulted, after complete correction of the anomalies, from heart failure One patient with congenital aortic stenosis and calcifications of the valve died on the 4th postoperative day of pulmonary complications, and 1 patient with multivalvular disease and cirrhosis of the liver died on the 4th postoperative day of hepatic insufficiency The remaining 8 patients were alive at the time the paper was written

Biochemical studies revealed metabolic acidosis as the most conspicuous change in the patients operated on with the aid of a heart-lung machine This change may also be found in patients subjected to heart operations without by-pass procedures, although it is then less pronounced The acidosis was regarded as detrimental, and its correction by means of bicarbonate infusion was recommended A moderate reduction in serum potassium and calcium levels was found to occur, but these levels were restored to normal spontaneously Other ionic changes were less constant and were considered to be unimportant Serum enzyme changes followed a pattern typical of myocardial infarction, and they may have been the result of the surgical trauma Bromsulphalein clearance tests provided valuable information concerning liver function, they showed that the liver was subjected to a particular stress which might have been due partly to acidosis The morphologic blood elements showed moderate changes in the course of the operation, but marked leukocytosis was present during the first postoperative week The blood platelet count dropped to a minimum within about 5 days after the operation but was restored to normal within 10 to 14 days

Chronic Leukemic Lymphadenosis and Pulmonary Resection The Question of Operability of Leukemic Patients H Effenberger and J Schulte Thoraxchirurgie 4 547-551 (April) 1957 (In German) [Stuttgart, Germany]

A case of lymphocytic leukemia was diagnosed in a 41-year-old man who had an open progressive pulmonary tuberculosis with large cavities During hospital treatment with a combination of chemotherapeutic and antibiotic drugs a regression of the tuberculosis with shrinkage of the cavities occurred Several weeks later, however, an exacerbation of the lymphocytic leukemia occurred with noticeable deterioration in the blood status After the chemotherapy was interrupted, the lymphocytic values became readjusted but the pulmonary tuberculosis again showed progression Resumption of the chemotherapy did not arrest the progression of the tuberculous process Since the lymphadenosis seemed to have a protracted chronic course and since damage of the erythropoietic system and, with this, reduction of hemoglobin formation could be excluded, it was decided to arrest the pulmonary tuberculosis by resection of the left upper lobe The intervention was tolerated without complications During the postoperative period an average of 300 cc of bank blood was administered once a week These transfusions resulted in a reduction of the leukocyte values Four weeks after the resection the blood status had been restored to preoperative values The patient has been working for about a year as a clerk At a follow-up examination 14 months after the operation both the chronic lymphocytic leukemia and the pulmonary tuberculosis seemed to be under control

Carcinoid Tumors Report of Case with Ileal Involvement C W Mayo and W M Hardy Proc Staff Meet Mayo Clin 32 254-257 (May 15) 1957 [Rochester, Minn]

The authors report the case of a 59-year-old man in whom exploratory laparotomy disclosed 20 carcinoid tumors involving a 2-foot segment of the ileum Metastasis was present in the liver His chief complaints had been intermittent episodes of crampy abdominal pain, distention, and borborygmi Occasional intestinal bleeding, attributed to hemorrhoids, had been present for a number of years This case was somewhat unusual in that the patient had none of the symptoms, such as flushing, asthma, cardiac murmurs cyanosis, edema, and diarrhea, usually attributed to the presence of serotonin

Management of Imperforate Anus L Shaffner North Carolina M J 18 202-207 (May) [Winston-Salem]

The management of the imperforate anus presents a twofold problem there is the immediate need to relieve intestinal obstruction, and a choice has to be made of a procedure that will ultimately allow the patient to have normal intestinal function and control This second consideration is often overlooked in the urgency to establish some type of opening Judging from referrals, there apparently still is a great temptation to do a minor stab" incision in the perineum or a colostomy The inadequacy of either procedure becomes apparent after 2 or 3 weeks in one or two ways Either the 'stab" wound will begin to form a stricture, causing another partial obstruction, or, in cases of rectourinary fistulas, chronic urinary infection develops even in the presence of a colostomy After these complications have developed, surgical attempts at secondary repair are much more difficult Initial repair of imperforate anus should not only relieve the obstruction but promise normal intestinal control and function Accurate diagnosis as to the type of anomaly, with or without a perineal, urethral, vesicle, or vaginal fistula, is essential to adequate treatment Other serious anomalies involving the heart, esophagus, and urinary tract are common and should be sought for

The membranous type of imperforate anus can be easily treated by simple anoplasty In the imperforate type, with the rectal pouch 1 5 cm or less from the anal skin, a perineal approach is usually possible and should be attempted With a higher pouch, especially in the male with a rectourethral fistula, an abdominoperineal pull-through procedure is indicated Two of the 9 deaths that occurred in the 41 patients whose cases are reviewed by the authors were attributed to operation for imperforate anus Follow-up ranging from 1½ to 13 years in primary perineal procedures showed good to excellent results in 10 cases, in 3, wound breakdown or stricture was noted when the patient was last seen Of 7 patients undergoing abdominoperineal repair, 3 have had good function after 2 to 4½ years, 2 infants were recently operated on, and 2 have strictures requiring further surgery All patients required postoperative dilatations, and about half needed an additional minor anoplasty Colostomy should be used only as a temporary measure to help handle complications The earlier definitive repair is done, the better is the chance for normal control and function

The Fate of Esophageal Varices in Cirrhosis Following Surgical Portal Decompression E D Palmer Gastroenterology 32 861-867 (May) 1957 [Baltimore]

Success of surgical portal decompression in the treatment of esophageal varices secondary to cirrhosis must be measured largely in terms of prophylaxis against future hemorrhage This report deals with the fate of varices in patients with cirrhosis, as judged by esophagoscopic measurement, following portacaval shunt, splenorenal shunt or without a surgical shunt Sixty-three patients with cirrhosis proved by liver biopsy were followed by periodic esophagoscopic examinations for up to 63 months following surgical portal decompression for esophageal varices An end-to side portacaval shunt had been made in 49 patients, and an end to-side splenorenal shunt in 14 patients The control group consisted of 45 patients for whom shunt was recommended but who refused the operation Portacaval shunt proved far more effective in reducing portal pressure and eliminating varices than did splenorenal shunt The latter operation gave good immediate results, but as time went on the varices tended to become worse and the portal pressure rose progressively With portacaval shunt, on the other hand, the immediate results were excellent and later any remaining varices tended to disappear or to become very much smaller The varices of the cirrhotic patient may disappear spontaneously without the operation, but there will probably be a return in all cases as time goes on Esophageal varices secondary to cirrhosis are vacillating structures influenced by a head of portal pressure which is constantly changing Variations in portal pressure continue after surgical portal decompression, but at much reduced levels

Bacteriological Experiments with Surgical Plastic Dressings G R Wallgren Acta chir scandinav 112 161-169 (No 3-4) 1957 (In English) [Stockholm]

Five plastic solutions recommended for use as surgical dressings were tested in vitro and in vivo These are (1) Bonoplast, an acrylic resin dissolved in ethyl acetate with the addition of a plasticizer, (2) Aeroplast, an ethyl acetate solution of copolymers of hydroxyvinyl chloride acetate and sebacic acid 9 3% by weight and modified maleic resin ester 3 1% by weight, with fluorochloro-hydrocarbon gas as a propellant, (3) Newskin, consisting of pyroxylin 6 9%, camphor 0 6%, castor oil 3%, butyl alcohol 5%, ethyl acetate 57 3%, and ethyl alcohol 25%, (4) Nobecutan, consisting of a 4% by weight solution of polymetacrylic acid ester with an ether bridge in the alcohol component, and (5) Portex plastic skin, consisting of phenyl salicylate 10%, resorcinol 5%, egenol 25%, and a proprietary Portex double methyl ester of acrylic resin The results of more than 2,000 bacteriological tests made on culture plates, principally on blood agar, and on patients' intact skin, showed that (1) the plastic solutions listed were sterile in themselves, (2) on the addition of certain bacteria the plastic solutions again became sterile after a certain maximum interval, (3) a zone of inhibition at the edge of or above the plastic film was produced only by Nobecutan, (4) the microorganisms tested penetrated the plastic films, but macroscopic growth was not always visible under the films and through-growth did not occur when the films were made a little thicker than normal, and (5) a slight reduction appeared in the bacterial flora underneath the plastic films

The plastic films are superior to cotton-wool dressings in many regards If all the qualities of the tested plastics are taken into account, Nobecutan and Aeroplast are better than the other products A plastic film is suitable as a mechanical protection for preoperative covering of the skin and as wound dressing for clean wounds in otherwise healthy skin The scope of the antiseptic effect of a plastic film in which disinfectants have been incorporated is not yet sufficiently guaranteed for plastic film alone to replace all surgical cleansing of the skin, but an effect like that exerted by Nobecutan is not without significance A film thickness of from 60 to 90 μ is recommended for Nobecutan, but to achieve this film thickness 4 to 5 coatings by spray were always required

Cholesterosis of the Gall Bladder W F Mitty Jr and L M Rousselot Gastroenterology 32 910-916 (May) 1957 [Baltimore]

Cholesterosis of the gallbladder has been known as a pathological entity since 1857, but a clear understanding of its pathological process is largely due to Boyd's studies, reported in 1923 In cholesterosis the lipoid is usually most abundant in the epithelium covering the villi of the mucosa Cholesterosis of the gallbladder should be reemphasized, because it is often neglected in the differential diagnosis of biliary tract disease The true incidence of the condition is difficult to ascertain, as it varies between autopsy material and surgical specimens In order to determine if a gallbladder obtained at autopsy is involved with cholesterosis, the examination must be accomplished within 3 hours of death, before autolysis of the mucosa takes place Gallstones and cholesterosis often concur, and it has been stated that cholesterosis without calculi is of no clinical significance and that cholesterosis per se does not produce symptoms It is this contention the current study purports to refute

The authors found that the diagnosis of cholesterosis was verified in 70 of 1,054 patients by pathological examination of the removed gallbladder In 38 of these 70 patients no stones were associated with the cholesterosis Abdominal pain was noted in 34 of 38 patients, 20 of these patients located it in the right upper quadrant, 4 had colicky pain localized to the periumbilical region, and 10 complained of epigastric pain In 19 patients the pain was referred to either the shoulder or the back The mechanism of pain in this disease, so similar to true biliary colic, is not clearly understood Cholecystography was performed in 28 of the patients It revealed normal function in 14 and impaired function in 9 In 5 the gallbladder was not visualized, but in 2 of these 5 calculi were found There was little correlation between the abnormal cholecystograms and the histological examinations of the gallbladder Of the 14 patients who had either impaired function or nonfunction of the gallbladder, only 4 had microscopic evidence of an associated chronic cholecystitis

The patients presenting normal cholecystograms but classic symptoms of gallbladder disease represent a challenge to the internist and the surgeon It is in this group of patients that duodenal drainage is indicated, and cholesterol crystals, if found, will indicate the diagnosis of cholesterosis It is only under these circumstances that a cholecystectomy is justified Without a positive duodenal drainage study and in the presence of a normal cholecystogram and normal operative findings no indication for cholecystectomy exists The authors were able to follow 32 of the 38 patients and found that 28 of the 32 were free from symptoms The other 4 still had symptoms, but in these the predominating complaint preoperatively was not pain but heartburn, gaseous eructation, and flatulence The treatment of choice is cholecystectomy Cholesterosis is probably a local manifestation of a systemic disease involving a disturbance of cholesterol metabolism Its focal occurrence in the gallbladder often presents a clinical pattern similar to chronic cholecystitis with or with cholelithiasis

Blood Vessel Replacement Therapy F N Cooke J Florida M A 43 1109-1116 (May) 1957 [Jacksonville]

Of 46 operations in which blood vessel transplants were used to reconstruct arterial continuity, 3 were performed as emergency procedures for an aneurysm that had ruptured, 16 grafts were placed in the abdominal aorta as an elective procedure, 6 were placed in the thoracic aorta, and 21 were placed in peripheral vessels Nine of the 46 patients died, an operative mortality of 19 1% The results in the patients who survived the operation for aneurysm were gratifying Peripheral circulation was adequately reestablished in all Only 2 of these patients died in the late postoperative period, 1 of them died of malignant disease of the prostate and the other of a ruptured abdominal aneurysm after a successful transplant for a thoracic aneurysm Autopsy was performed in both and revealed that the homologous graft was functioning well at the time of death Of the 21 peripheral transplants 14 were used for traumatic arteriovenous fistula and aneurysm In 9 of the 14 patients, autogenous vein grafts and in 5, homologous arterial grafts were used These transplants have functioned in a highly satisfactory manner for many years Ten of the 46 operations were performed for obliterative arterial disease, and the results were not as good as in the case of those performed for aneurysm The disease is diffuse, and there may be occlusion distal to the by-passed segment Most of the failures were attributed to the skip areas of obliteration, i e, to the nature of the arteriosclerotic disease itself

For short defects in peripheral vessels such as have been observed in traumatic aneurysm or arteriovenous fistula, the autogenous vein graft offers an excellent method of reestablishing vascular continuity The homologous arterial graft which has been sterilized and stored in a frozen state has given highly satisfactory results in the surgical treatment of aneurysm When normal or near normal proximal and distal arterial segments are present, restoration of vascular continuity can be accomplished with certainty In obliterative arterial disease it is the disease itself which in most patients determines the success or failure of the replacement therapy

Cancer-Cell Seeding of Operative Wounds as a Cause of Failure in the Surgical Treatment of Cancer R R Smith and A W Hilberg J Maine M A 48 151-156 (May) 1957 [Brunswick]

Cancer cells have been demonstrated on instruments, in wash water, and on the surface of organs A study was undertaken at the Clinical Center, National Institutes of Health, to determine how frequently tumor cells could be identified in washings taken from operative wounds Patients with cancer that by accepted standards was considered operable but by reported end-results would have a high incidence of local recurrence were treated by the usual en bloc cancer surgery Just before closure of the skin flaps, after the surgical removal of the primary tumor and its lymph node drainage area, the wound was thoroughly washed with sterile isotonic sodium chloride solution in a fine spray The washings were collected in a glass container and mixed as soon as possible with the fixative of 70% or 95% alcohol

The washings were then centrifuged at 2,500 rpm Part of the resulting sediment was covered with 10% formalin and the button of fixed sediment embedded in paraffin and sectioned in the routine manner for tissue sections Another part of the sediment was smeared directly on clean glass slides, which were then immersed in a solution of equal parts of 95% alcohol and ethyl ether After 30 minutes, and while wet, the slides were stained by routine nuclear and cytoplasmic stains The Papanicolaou staining technique was the standard method used The slides were screened by technicians trained to interpret exfoliative cytologic material, and cells or groups of cells to be studied by the pathologist were marked

In the first 113 patients studied, cancer cells were demonstrated in 31 (positive results), and in an additional 16 patients the cytologist could not be definitely sure as to the nature of the cells and reported the washings as suspicious In the remaining 66 patients, no tumor cells were found The significance of these results is difficult to determine at this time Many of the patients have not had sufficient time to manifest their metastases Since the wounds were thoroughly washed, it will be difficult to determine just what the washing alone will do to the incidence of local recurrences There are 7 known seeded recurrences in the operative area in patients with positive washings and an additional 2 recurrences in patients with suspicious washings There have been recurrences in 7 patients whose washings were free from tumor cells It is believed that in some patients local seeding is the cause of failure of surgical treatment If effective chemotherapeutic agents are discovered which can selectively destroy cancer cells that either become embedded in the wound or break off and are free in the blood or lymph channels, effective cancer therapy will be available

PEDIATRICS

Visceral Larva Migrans A Cause of Severe Eosinophilia

F C Vanore M Ann District of Columbia 26 245 247 (May) 1957 [Washington, D C]

Visceral larva migrans results from the ingestion of dirt infested with eggs of Toxocara canis, a parasitic round worm whose natural host is the dog T canis is especially seen in areas where the soil is sandy, warm, and moist It is one of the commonest parasites found in the soil About 90% of dogs under 2 years harbor the round worm The fertile eggs are passed in the dog's stools and contaminate the soil, after 3 weeks the eggs become embryonated and may be swallowed by man, especially children, who do not observe sanitary precautions The larvae hatch, penetrate the intestinal wall, and migrate to various organs The larvae usually remain in the liver, where they become encapsulated and perish after several months T canis, unlike Ascaris lumbricoides, never reaches a mature form in man, since the natural host is the dog, and therefore stools of a suspected patient will be negative for ova and parasites Visceral larva migrans is related to cutaneous larva migrans or creeping eruption in that both are caused in the infective stage by larvae of nematode parasites specific for lower animals

The clinical symptoms of children who have this disease are protean and may be mistaken for Loffler's syndrome and tropical eosinophilia Fever, leukocytosis, hyperglobulinemia, and pulmonary changes are common The pulmonary changes are suggestive of patchy pneumonitis and Loffler's syndrome Clinically the findings are akin to bronchitis and bronchopneumonia The patient may exhibit malaise, pallor, anorexia, muscle aches and pains, nausea and vomiting, and jaundice Hepatosplenomegaly is common An impetiginous, pruritic type of skin rash may appear on the trunk and extremities White blood cell counts may range from 15,000 to 80,000 per cubic millimeter of blood, with an eosinophilic percentage between 20 and 80 The disease is highly probable in an infant or child, usually between the ages of 1½ to 3 years, who has a history of ingestion of dirt with a persistently high eosinophil count A definitive diagnosis can only be made by liver biopsy and identification of the larvae on serial sections Although usually benign and self-limiting, the disease may cause severe symptoms Treatment of the disease in man has been unsuccessful to date, but cortisone may be used empirically

Calcification of Intervertebral Discs in Children Report of a Case

M B Mann North Carolina M J 18 195-197 (May) [Winston-Salem]

While calcifications of intervertebral disks are usually degenerative processes in adults and of negligible clinical significance, there have been few reports of radiologically demonstrable disk calcifications in children The case of the 9 year-old Negro boy reported in this paper was the 21st reported in the English language literature The boy was hospitalized with a history of pain and stiffness in the neck and shoulder which gradually subsided in the course of several weeks, but, because of these symptoms and abnormal findings in roentgenograms of the cervical portion of the spine, he was referred to the hospital The right shoulder was held higher than the left, with the head tilted slightly to the right There was fairly good range of motion of the neck, but extension produced sudden pain over the anterior portion of the right shoulder Lumbar lordosis was prominent Submandibular nodes were slightly enlarged The lungs were clear A systolic murmur was heard over the precordium Slight weakness of the deltoid and right biceps and triceps was demonstrated Physiotherapists observed weakness of the right shoulder and arm, especially in the deltoid and latissimus dorsi muscles A roentgenogram of the chest and fluoroscopic examination of the heart showed no abnormalities, but roentgenograms of the cervical and lumbar spine showed calcification between the 4th and 5th cervical vertebrae and the 5th lumbar and 1st sacral vertebrae An orthopedic consultant concurred with the diagnosis of calcified intervertebral disk syndrome of childhood Follow-up examination 6 months later revealed that the calcification had disappeared from the cervical region but was still present in the lumbosacral region

In 16 of the 21 children with intervertebral disk calcifications local symptoms occurred at the site of the calcification The other 5 cases were diagnosed on the basis of incidental findings noticed during the examination of patients with seemingly unrelated illnesses The reversible calcification in children is quite different from the irreversible calcification of the spine in adults It is possible that the variations in vascularization of the disks in childhood and in adult life may account for these differences Up to the age of 10 or even 20 years there is a profuse blood supply to the intervertebral disk through vascular channels which are embedded in and perforate the cartilaginous plates These vessels originate in the spongiosa of the vertebral bodies and are later obliterated by fibrous changes Two factors, either singly or together, could account for the transient calcification phenomena Trauma to the highly vascularized disk in childhood may result in hemorrhage and hematoma formation and subsequent calcification The rich blood supply would probably explain the eventual clearing of the calcification In addition, calcification may be the result of infectious processes involving the disks Signs of infection such as fever, leukocytosis, pain, and increased sedimentation rate were noted in some of the patients

Congenital Aortic Stenosis in Children B Landtman and E I Wallgren Ann Paediat Fenniae 2 259-269 (No 4) 1956 (In English) [Helsinki]

Congenital aortic valvular defects are comparatively rare A total of 6,400 children was examined at the cardiac clinic of the Children's Hospital, University of Helsinki The clinical diagnosis of congenital aortic stenosis was established in 24 children between the ages of 3 months and 16 years Two of the patients were siblings The children were not cyanotic The aortic stenosis was present as an isolated lesion in 17 One had aortic incompetence, 4 had a patent ductus arteriosus, 2 had coarctation of the aorta, and 1 presented clinical signs suggestive of a ventricular septal defect A rough systolic murmur, usually accompanied by a thrill, maximal over the aortic area, transmitted to the vessels of the neck, was the outstanding feature of aortic stenosis Phonocardiograms showed a diamond-shaped systolic murmur, transmitted by the blood stream as well as along the walls of the blood vessels Most of the children showed radiological evidence of left ventricular enlargement, which was more conspicuous in the children with complicated lesions The electrocardiograms revealed different degrees of left ventricular hypertrophy or strain All but one of the children with isolated aortic stenosis were asymptomatic The patients with patent ductus arteriosus improved after ligation of the ductus None of the patients died during the follow-up period, which varied from 1 month to 3 years No attempt was made to differentiate clinically between valvular and aortic stenosis, although angiography was sometimes of help in separating the 2 types

A Fatal Granulomatosis of Childhood The Clinical Study of a New Syndrome H Berendes, R A Bridges and R A Good Minnesota Med 40 309-312 (May) 1957 [St Paul]

The authors report observations and studies on 4 male children who were observed at the University of Minnesota Hospitals since 1950 and who had a hitherto unreported syndrome consisting of chronic suppurative lymphadenitis, hepatosplenomegaly, pulmonary infiltrations, and eczematoid dermatitis about the eyes, nose, and mouth During the first year of illness the chronic lymphadenitis was the most prominent clinical manifestation This process seems gradually to abate while the pulmonary disease and general debilitation dominate the clinical picture during the later stages of the disease Death occurred in 3 patients after an illness of from 2 to 3½ years One child has had his disease for a little over 1 year All patients were boys One child had a suggestive family history In 3 previous generations on the maternal side of this boy s family, with the exception of the boy's grandfather and great-grandfather, all the males died during infancy with a syndrome described as either boils and septicemia or scrofula The maternal grandfather, who survived, still has a mass in the cervical area Numerous laboratory studies were made on the 4 children, and autopsies and pathological studies were made on the 3 who died

The authors believe that the symptoms are the result of a generalized granulomatous process They were associated with a striking hypergammaglobulinemia The authors differentiated this new syndrome from recognized forms of infectious and noninfectious diseases producing granulomatous processes in childhood, but they feel that there is a remote possibility that this malignant granulomatous disease is actually a childhood expression of sarcoidosis The treatment of these children was largely empirical Chloromycetin and erythromycin were used in high doses for periods of at least 1 month Combinations of penicillin and sulfadiazine and the various tetracyclines were used for periods of one to several months Novobiocin was also tried without effect, and aminosalicylic acid, streptomycin, and isoniazid were used without effect in 2 of the patients Relentless progression seems to be the most characteristic feature of the syndrome

DERMATOLOGY

Fatal Agammaglobulinemic Progressive Vaccinia H M Lewis and F C Johnson A M A Arch Dermat 75 837-844 (June) 1957 [Chicago]

The recovery of an individual infected with vaccinia virus reflects his ability to produce adequate, appropriate, antivaccinal antibodies Failure to produce such bodies may be due to agammaglobulinemia or dysgammaglobulinemia Dysgammaglobulinemia differs from agammaglobulinemia in that it is amenable to therapy (hyperimmune vaccinia gamma globulin), runs a prolonged course, and represents a qualitative rather than a quantitative defect in gamma globulin formation In the absence of gamma globulin, virus-neutralizing antibody is not formed Inability to produce adequate virus-neutralizing antibody results in the initial site of vaccination undergoing enlargement and necrosis Many new concomitant lesions resulting from hematogenous virus dissemination undergo a similar metamorphosis, showing no sign of healing, with ultimate destruction of the host by the virus This entity, known as agammaglobulinemic progressive vaccinia, is usually fatal within 2 months or less

Dermatitis Medicamentosa Due to Antipyrine C B Kennedy, F H Davis, V M Henington and M J Sternberg A M A Arch Dermat 75 826 836 (June) 1957 [Chicago]

During the period beginning July 1, 1949, and ending May 1, 1956, 132 patients were admitted to the dermatologic wards of Charity Hospital of Louisiana in New Orleans with a diagnosis of dermatitis medicamentosa Included in this group were 27 Negro patients in whom the eruptions and other symptoms were clearly attributable to a preparation for the treatment of colds, manufactured under the name 666 (containing 0 6 Gm of antipyrine) The lesions noted were large, widespread, and numerous, involved considerable mucous membranes, and were of the fixed eruptive type Druggists have reported an increase in the sale of this preparation, and this increase is in direct proportion to the increasing number of reactions observed The group of 27 patients observed contained 21 males ranging from 21 to 64 years of age Seventeen of these patients had taken 666 in the past, but only 9 reported a previous reaction Without exception, where there had been more than one reaction, succeeding reactions were even more severe and of a more frequent nature

Members of a white group reported that they used the preparation only for a specific medical reason, while members of the Negro group were more inclined to use it for a hangover, a good cleaning out," and purgative action The dose in Negro patients was consistently larger than indicated in the directions and was taken quite frequently, in contrast to that in white patients, who generally followed directions The increased sensitivity to reaction among Negroes may be described as cumulative with patients continuing to use the preparation in spite of both past and current reactions

The Diagnosis of Lupus Erythematosus A H Slepyan, D V Frost, L R Overby and others A M A Arch Dermat 75 845 849 (June) 1957 [Chicago]

Lupus erythematosus, because of its protean manifestations, has often posed a difficult diagnostic problem in spite of many well-established criteria The ratio of bound to free pantothenic acid levels of whole blood in patients with discoid and systemic lupus erythematosus is constantly lower than those found in normal controls Patients with lymphocytic infiltration of the skin exhibited a normal to high bound-to-free pantothenic acid ratio Patients with lymphoblastoma showed an abnormally low bound-to-free ratio, which suggests that the same inherent enzymatic defect was peculiar to both lymphoblastoma and discoid and systemic lupus erythematosus Similar findings regarding systemic and discoid lupus erythematosus suggest that they are one and the same, as the same enzymatic defect is manifest in both stages of disorder

Cutaneous Candidiasis A Clinical and Therapeutic Study S A Simuangco, M C Fernandez, P O Campos and others J Philippine M A 33 257-270 (April) 1957 [Manila]

A group of 147 patients who were suspected of having fungus diseases of the skin were studied with the aim of determining the incidence of candidiasis (moniliasis) in relation to other mycotic infections For Candida alone, 50 3% of the patients were found to be positive, indicating that this was probably the primary cause, whereas 6 8% were positive for Candida and other fungi, indicating that the candidiasis was superimposed The over-all incidence of candidiasis was 57 1% It appeared that candidiasis is more common in fungous diseases than it was thought to be, according to other reports One hundred thirty-one patients with cutaneous candidiasis were given nystatin tablets in doses ranging from 250,000 to 500,000 units 3 to 4 times daily, ointment and powder were applied once or twice a day The majority of the patients responded to the drug within the first week The lesions of the 6 cured patients (4 58%) disappeared within 14 to 56 days Follow-up culture for Candida albicans gave negative results in 2 of these patients Remarkable improvement was observed in 80 of the 131 patients (61 06%), 12 had slight response (9 16%), and 24 had no response at all (18 39%) The presence of secondary changes, such as eczematization and secondary infection, should be cleared up before treatment with nystatin is started Certain predisposing factors such as diabetes, obesity, malnutrition, or occupation need a previous correction An additional treatment with hydrocortisone might produce better results in the complete cure of cutaneous candidiasis

UROLOGY

Bladder Neck Obstruction and Associated Lesions in Children E Burns, E H Ray Jr and J W Morgan J Urol 77 733-740 (May) 1957 [Baltimore]

Obstructive lesions of the lower urinary tract in children are now recognized as common Changes in the bladder and upper urinary tract are in proportion to the degree of obstruction and the length of time it has existed Since these lesions are congenital, the duration of the obstruction is determined by the age of the child Associated lesions are frequently encountered In the 129 children with congenital bladder neck obstruction treated surgically by the authors at the Ochsner Clinic and Charity Hospital in New Orleans, the types of lesions and their distribution were as follows congenital prostatic valves in 3 congenital hypertrophy of the verumontanum in 2, and congenital hypertrophy of the internal sphincteric area in 123 The remaining patient had a greatly dilated urinary tract when examined at the age of 6 weeks An obstructive lesion was questionable in this child, and failure of normal development appeared more likely The signs and symptoms produced by bladder neck obstruction in children show wide individual variation Perhaps the most common finding that leads to investigation of the urinary tract is pus in the urine Infected urine was found in 79% of the 129 children, and 89% of these had suffered recurrent attacks of chills and fever Infection in these patients is a complication of obstruction, frequently a late one, and the fact that urinary infection led to the initial urologic investigation indicates that earlier symptoms were overlooked or considered insignificant Importance should therefore be attached to any variation from the normal voiding pattern in a child Other symptoms were frequency and straining to urinate, urgency, enuresis, overflow incontinence, acute retention, and hematuria The incidence of acute retention in children is low Acute retention occurred in only 5 of the 129 children Gross hematuria occurred in only 6 of this group It usually occurs while the patient is straining to urinate and is more likely to happen in those with an acute infection

Changes in the urinary tract produced by bladder neck obstruction in children vary somewhat from those observed in adults The period during which hypertrophy of the bladder musculature may compensate for the increased difficulty in performing its function appears to be short in children, giving way to such rapidly progressive dilatation that the bladder becomes a large atonic sac Vesicoureteral reflux is also encountered more frequently in children In those patients with reflux varying degrees of hydronephrotic atrophy of the renal cortex will be found Vesical diverticula of clinical significance occur less frequently in children They were found in only 2 of the 129 children The diagnosis of obstruction of the lower urinary tract in children requires, in addition to routine chemical and bacteriological studies of the urine and renal function tests, specific urologic studies These include excretory urography, retrograde cystography, cystoureteroscopic examination, and retrograde pyeloureterography Treatment of bladder neck obstruction in children is surgical removal of the primary obstructive lesion by transurethral resection or through the suprapubic transvesical approach

Local Injections of Hydrocortisone for the Effective Treatment of Circumscribed Strictures of the Urethra M K Lyons and C D Bonner J Urol 77 741-755 (May) 1957 [Baltimore]

The authors report experiences with this type of treatment in 53 patients with 56 strictures of the urethra and the meatus There were 18 strictures of the meatus 15 of the anterior urethra, 18 of the membranoprostatic junction and 5 of the posterior urethra An aqueous suspension of hydrocortisone was injected directly into the tunica propria at the base of the stricture at 2 clock positions 5 and 7 or 3 and 9 No anesthesia was required in the meatal stricture, and the injection was done directly without the aid of urethroscopy, a 2 cc syringe and a 22-gauge needle being used Strictures of the anterior and posterior urethra were located and visualized through the McCarthy foroblique panendoscope, and injection was done with an especially devised endoscopic needle passed through the panendoscope and inserted into the tunica propria beneath the stricture under direct vision The most important feature of this insertion is to get the needle well under the mucosa and into the tunica propria underlying the stricture before the hydrocortisone is injected The injection was done under local intraurethral anesthesia with 1 500 nupercaine solution or, more desirable, under low spinal or general anesthesia as the case indicated With each treatment the stricture was first dilated to its limit of distensibility without rupture

Total dosages of 25 mg to 150 mg of hydrocortisone in from 1 to 8 injections were administered When more than 1 injection was given, the successive ones were done in most instances at intervals of 2 days Total dosage and interval of injections varied Patients received prophylactic chemotherapy or antibiotic therapy, however, no complications resulted from the omission of this therapy in more recent cases Fifty-one of the 56 urethral and meatal strictures were cured by the local injection of hydrocortisone into the tunica propria below 2 clock positions of the urethral stricture Cure was usually obtained with 3 or fewer injections Two dense elongated strictures and 3 multiple strictures not amenable to this therapy were eventually cured by internal urethrotomy and injection of the incision site with hydrocortisone

OPHTHALMOLOGY

Treatment of Retinal Artery Occlusion L M Weerekoon Am J Ophth 43 947-950 (June) 1957 [Chicago]

The pathology of retinal artery occlusion is still being debated Three causes have been suggested (1) embolism, (2) local vascular accident (thrombus), and (3) arterial spasm Of these, the first has been rejected Thrombosis is generally thought to be the cause of retinal occlusion today, but the author believes that arterial spasm is always present, either as the primary cause or secondary to a thrombus Patients with retinal artery occlusion can be divided into 2 groups (1) young adults who show no abnormality other than cold fingertips or other evidence of vasomotor instability, in whom arterial spasm is the primary cause of occlusion, and (2) persons who are past middle life and who have arteriosclerotic disease and/or hypertension and thus are predisposed to develop thrombi The author feels that treatment of retinal occlusion should be based on the premise that every case involves a spasm Retrobulbar injection of a vasodilator is the best of the medical methods of treatment, while stellate ganglion block, in an attempt to reduce sympathetic overactivity, is apparently an effective surgical measure Seventeen patients were given retrobulbar injections of Priscol (imidazoline hydrochloride) or Ronicol (β-pyridyl-carbinol) followed by systemic treatment, and useful vision was restored in many of the patients Priscol is contraindicated in patients with coronary disease and peptic ulcer because of its histamine-like action

INDUSTRIAL MEDICINE

Organic Phosphate Insecticide Poisoning An Agricultural Occupational Hazard C S Petty J Louisiana M Soc 109 158-164 (May) 1957 [New Orleans]

Four cases of organic phosphate insecticide poisoning incurred during the crop-dusting season are reported in patients between the ages of 15 and 44 years The first patient was employed as a "mixer" of insecticides and was wearing a raincoat, gloves, and a respirator when opening cans of 25% Parathion Since he was adequately protected it may be assumed that the mask leaked or the filter elements may have been exhausted by long use In this patient, mild Parathion poisoning was manifested by profuse sweating, a marked tremor of the hands, a sluggish reaction of normal-sized pupils to light, and a blood cholinesterase level of about 50% of normal The second patient was spraying methyl Parathion on crops with his aeroplane A slight leak developed in the insecticide storage tank in the front cockpit of the aircraft, permitting the insecticide to leak onto the pilot's leg for several days Weakness, abdominal cramping, nausea, vomiting, and diarrhea occurred When he was admitted to hospital his pupils were narrow, he was profusely sweating and salivating and had a coarse tremor of the hands The pilot of an airplane faces an additional hazard from organic phosphate poisoning in that the pupils may be narrowed and accommoda tion may be impaired, making judgment of depth and distance poor The third patient applied tetraethylpyrophosphate with a small hand-sprayer to a small crop No protective clothing was worn and no respirator was used Weakness, muscular twitching, abdominal cramps, nausea, and vomiting occurred within 2 hours and the blood cholinesterase level was 5% of normal Tetraethylpyrophosphate is the most potent of the organic phosphate insecticides and should never be handled without adequate protective clothing and equipment The 4th patient was employed as a 'flagger' in the cotton fields He was exposed for several days to a spray of 1% methyl Parathion released from an aeroplane Dizziness and vomiting occurred The next day cigarettes made him feel sick, and his blood cholinesterase level was about 40% of normal

All 4 patients were treated successfully with atropine The recommended initial dose of the drug is 2 to 4 mg (1/30 to 1/15 grain) given intravenously or intramuscularly If, 10 to 20 minutes after such a trial dose, drying of the skin and mucous membranes and dilatation of the pupils have not occurred, the patient may be given large amounts of the drug (up to 30 mg in the first hour) In giving the atropine, the effects of the drug are 'titrated' against the effects of the poison Artificial respiration may be necessary for the comatose patient The contaminated clothes of the victim must be removed and the surface of the body washed in an effort to prevent continuing absorption of the agent through the skin Repeated atropinization may be necessary

Absence of Raynaud's Phenomenon in Workers Using Vibratory Tools in a Warm Climate T A Lloyd Davies, E M Glaser and C P Collins Lancet 1 1014-1016 (May 18) 1957 [London]

The Raynaud phenomenon is induced by exposure to cold and precipitated by the use of vibratory tools In cold weather people working with vibratory tools often display this phenomenon on their way to work, especially if they use a bicycle or a motor-cycle, but symptoms may disappear during work when the body warms up Raynaud s phenomenon is unknown among men using vibratory tools in Singapore, and it was therefore of interest to find out whether it is either masked or prevented by a warm climate Singapore is within 1½ degrees of the equator, and its climate is uniformly warm Studies were made on 31 workers who had been using vibratory tools in a Singapore dockyard Most of them had done this work for more than 3 years and 10 of them for more than 15 years All tests were made in a cool room at 10 5 C (51 F) while the men wore tropical clothes but no shoes or socks A period of not less than 75 minutes was allowed to enable the men to complete thermal adjustments After the preliminary period each man immersed his right hand and wrist in water at 10 C (50 F) for 10 minutes

None of the dockyard workers showed any signs of Raynaud s phenomenon The evidence suggests that vibration induces the Raynaud phenomenon only if there is also intermittent cooling of the body and of the hands The authors conclude that an investigation on the lines of the present experiment, involving thorough cooling of the whole body as well as immersion of the hand, would show up potential sufferers from the Raynaud phenomenon If all those intending to use vibratory tools were tested in this way, it would be possible to classify Raynaud's phenomenon as an industrial disease Thorough general warming of the body and hands before starting work in places heated to relatively high environmental temperatures might be advantageous

PUBLIC HEALTH

Preventive Treatment of Tuberculosis in Italy The Present-Day Approach to the Problem S Taronna Clin pediat 39 31-39 (Jan) 1957 (In Italian) [Bologna, Italy]

The author describes 3 periods of the campaign against tuberculosis that has been waged in Italy since 1927 The first period, from 1927 to 1940, was characterized by the obligatory establishment of centers for the fight against the disease Problems such as early diagnosis and assistance for admission to health centers were solved considerably, and the mortality rate diminished markedly The incidence of infection and the mortality rate increased markedly during the second period, which lasted from the beginning of the war to the immediate post-war years Antibiotics reduced markedly the mortality rate during the third period, from the post-war years to the present day A tendency toward chronic forms of the disease, the large number of infectious sources, and resistance to antibiotics are the major problems that the campaign for the prevention of tuberculosis faces in Italy today Mass roentgenologic examination reduced the morbidity rate of the city of Venice from 5 23% in 1950 to 1 02% in 1955 Very good results have been obtained with vaccination Only 0 36% of 3,952 children that were vaccinated contracted tuberculosis, 2,742 of these children lived in a contagious environment, and 0 51% of these contracted tuberculosis The author thinks that the next step of the campaign is to improve the conditions of chronic patients, who increase continuously in number

Grand Rapids Fluoridation Study—Results Pertaining to the Eleventh Year of Fluoridation F A Arnold Am J Pub Health 47 539-545 (May) 1957 [Albany, N Y]

The results of 11 years of water fluoridation in Grand Rapids, Mich , for both deciduous and permanent teeth have been summarized The results of this study, together with others which have been conducted for similar periods, indicate the feasibility of this procedure for the control of dental caries In all studies the findings show a reduction of 60 to 65% in the prevalence of caries in the permanent teeth of children born subsequent to the change in water supply Furthermore, the evidence strongly suggests beneficial effects on teeth which were formed, or erupted, prior to the initiation of water fluoridation

BOOK REVIEWS

Principles of Surgical Physiology By Harry A Davis, M D, C M F A C S, Clinical Professor of Surgery and Director of Surgical Research, College of Medical Evangelists, Los Angeles Foreword by Lester R Dragstedt, Professor of Surgery and Chairman of Department, University of Chicago, Chicago Cloth $20 Pp 841 with 49 illustrations Paul B Hoeber, Inc (medical book department of Harper & Brothers), 49 E 33rd St New York 16 1957

This book is a well-written condensation of currently available information It is primarily a surgical textbook with emphasis on physiological aspects, for the author maintains a clinical approach throughout The usual presentation of the basic physiology of each system is included, but, in addition, most of the disease processes of interest to the surgeon are discussed specifically and symptoms and signs are correlated with physiological changes The book is divided into two sections The first consists of 13 chapters dealing with such general subjects as nutrition, cellular metabolism, surgical convalescence, and tissue transplantation The second section, also 13 chapters, is devoted to a more detailed presentation of each major system of the body—except the special senses Throughout the book and in an appendix are tables of chemical and physiological tests currently in use, including pulmonary function tests, data on cardiac catheterization, and tests of endocrine function In addition to normal values, changes resulting from specific lesions are recorded This is an excellent textbook for the young surgeon For the more advanced student, however, the coverage of many subjects is too brief, and discussion of controversial points is too limited or omitted The value of this volume would be enhanced by increasing the scope of the bibliography Nevertheless, this is one of the best works available on this subject

Ciba Foundation Symposium on the Nature of Viruses Editors for Ciba Foundation G E W Wolstenholme, O B E, M A M B, and Elaine C P Millar, A H -W C, A R I C Cloth $8 Pp 292, with 57 illustrations Little, Brown & Company, 34 Beacon St, Boston 6, J & A Churchill, Ltd, 104 Gloucester Place, Portman Sq, London, W 1, England, 1957

Since the Ciba Foundation was established in London in 1947 as an international educational and scientific center, it has arranged conferences and symposiums and arranged for publication of the proceedings In this 32nd book of the series, 17 eminent scientists give their ideas on such topics as the structure of viruses revealed by the electron microscope, the chemistry of viral mutants, ribonucleic acid in influenza virus, multiplication of animal and plant viruses, morphologic aspects of viral infections of cells revealed by fluorescent antibodies, the size and distribution of specific antigens in virus-infected tissues and their significance, and the interaction of phages with bacterial cell walls The papers and discussions show that a long road has been traveled from the point of departure—the mysterious filterable infective particle—to a typical virus particle envisioned as a structure made up of nucleic acid carrying genetic material and a coating of proteins with enzymes determining its antigenic specificity It is now known that the protein and nucleic acid portion of certain plant viruses can be dissociated and later recombined to form a reconstituted infective particle, making it clear that viral multiplication is a special case of protein biosynthesis

Aside from great intrinsic interest to biology, the implications of the phenomena analyzed and discussed extend far beyond the field of viral research and have many practical objectives They make it apparent that the solution of the problems of controlling viral multiplication by chemotherapeutic agents can come only through biochemical study of viruses Prevention of viral diseases requires either the preparation of purified vaccines or the selection of living vaccine strains appropriate to the purpose Why it is so difficult to prepare a formalin-treated poliomyelitis vaccine of constant value is partly explained From a human point of view, the important feature of any virus is its virulence The approach to the resulting problems is mainly academic in that it stresses the morphologic, physical, and chemical methods of developing hypotheses The biologist and the physician should take advantage of this opportunity to learn about the contributions being made by physicists and chemists to viral research This book requires careful study It is a rich source of critical information assembled in a well-printed, well-illustrated form It brings together scattered observations and facts by reviewing for the scientist certain phases of viral research Students of microbiology should broaden their horizons by reading this book

Understanding Surgery Edited and compiled by Robert E Rothenberg, M D Cloth $4 95 Pp 620, with 103 illustrations by Sylvia and Lester V Bergman McGraw-Hill Company, Inc, 330 W 42nd St, New York 36, 95 Farrington St, London, E C 4, England, 253 Spadina Rd, Toronto, Canada, 1955

This book was written for the laity Clarity has been maintained throughout by the use of nontechnical terms and simple pen and ink drawings Eight authors have collaborated on sections dealing with ocular surgery, otorhinolaryngology, neurosurgery, surgery of the neck and chest, abdominal surgery, urology, gynecology, orthopedics, and surgery of the superficial tissues Unnecessary overlapping of subject material has been avoided Although the technical material is excellent and timely, this is a glaring example of poor book making The pages have been placed off center and the sentences seem to run up and down hill It was indeed a strain on the eyes to attempt to read the book It may be that the reviewer's copy was a bad one and that in later copies these faults have been corrected The material contained in the book can be recommended to the lay reader

QUERIES AND MINOR NOTES

PROGNOSIS WITH AURICULAR STANDSTILL

To the Editor —*If sustained or prolonged auricular standstill, as demonstrated on the electrocardiogram, persists for more than a few seconds, what can be expected as to the prognosis and what would the etiology be suspected to be? Is this condition ever found in a situation where idioventricular rhythm has been established and in which the patient has survived for several weeks months, or years?*

Roy W Money, M D , Pulaski, Tenn

Answer —The diagnosis of auricular standstill may be difficult to make electrocardiographically It is assumed to be present when a nodal or idioventricular rhythm is present without visible P waves However, differentiation must be made from nodal rhythm with P waves buried within the QRS complexes and from auricular fibrillation with complete atrioventricular block When one labels a rhythm auricular standstill, it is assumed that there is complete sinus arrest, with block of retrograde conduction from the atrioventricular node, so that no impulse enters the auricular muscle from the nodal pacemakers In addition, the auricular myocardium is markedly depressed, so that no auricular foci are set up Auricular standstill has been produced experimentally after anoxemia, cooling of the sinus node, potassium poisoning, and carbon monoxide poisoning Carotid sinus pressure, coronary ischemia, and rheumatic myocarditis are other etiological factors The commonest clinical cause for this condition is overdosage with digitalis and quinidine It generally occurs in elderly patients with congestive heart failure, severe coronary disease, and ischemia of the myocardium It rarely occurs in the absence of organic heart disease The auricular standstill is usually transient and generally occurs when arrhythmias such as auricular fibrillation, are converted to normal sinus rhythm Not infrequently, however, it may last for several hours or days In one reported case, it lasted for 11 days There is no reason why it cannot last longer

The prognosis is poor The majority of patients with auricular standstill die within several days or weeks, but this is probably the result of the severe organic heart disease and heart failure rather than the impaired auricular conduction Treatment includes stopping the administration of digitalis and quinidine, if they are etiological factors, and administering atropine, ephedrine, or Isuprel Potassium salts may help if overdosage of digitalis is a factor The associated coronary ischemia and the cardiac failure must be treated

USE OF DIGESTIVE ENZYMES FOR EXUDATE OF OTITIS MEDIA

To the Editor —*Ear pathology that progresses from an acute otitis media to a subacute or a chronic otitis media with the development of a thick exudate has been observed in children After a myringotomy has been done and after this thick glue-like mucus has been aspirated from a child's ear, would it be harmful to inject an enzyme, such as Tryptar, in the middle ear?*

Ray M Moose, M D , San Bernardino, Calif

Answer —A digestive enzyme, such as Tryptar, or Caroid, a brand of digestive ferment derived from the Carica papaya, may be used to digest the thick mucus or the mucopurulent exudate of an acute, subacute, or chronic otitis media effectively and safely

EXOPHTHALMOS WITH CONJUNCTIVAL EDEMA

To the Editor —*What is the recent treatment for exophthalmos and conjunctival edema associated with toxic diffuse goiter (Graves' disease)?*

Henry G Kurz, M D , La Habra, Calif

This inquiry was referred to two consultants whose respective replies follow —Ed

Answer —The common type of exophthalmos associated with toxic diffuse goiter is that which parallels the course of the hyperthyroidism This is a benign form of exophthalmos which requires no special treatment other than correction of the hyperthyroidism Exophthalmos that is accompanied by conjunctival edema, chemosis, and extraocular muscle palsy is more likely to be the progressive or malignant type Wide variations in the course of the exophthalmos make it almost impossible to predict the eventual outcome in any particular case Furthermore, the unpredictable course makes it extremely difficult to determine whether improvement in the exophthalmos is due to a spontaneous remission or to the therapy that happens to be in use at the time

In general, there is no effective medical treatment for progressive exophthalmos If hyperthyroidism is present, it should be corrected in a positive manner by subtotal thyroidectomy after preparation with antithyroid drugs or with radioiodine (I^{131}) if the patient is over 50 years of age There is no conclusive evidence that progression of the exophthalmos is accelerated by the elimination of hyperthyroidism It is true that exophthalmos may progress after correction of hyperthyroidism with antithyroid drugs, with thyroidectomy, or with I^{131}, but it is also true that exophthalmos has progressed severely in the presence of active hyperthyroidism Elimination of hyperthyroidism is, therefore the first step in the treatment of exophthalmos

---

The answers here published have been prepared by competent authorities They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply Anonymous communications and queries on postal cards cannot be answered Every letter must contain the writer's name and address but these will be omitted on request

Care of the protruding eyes should include elevation of the head of the bed at night, protection of the cornea during the day by the use of glasses, warm compresses to the eyes three or four times a day, application of protective ointments at bedtime to avoid drying of the cornea, prompt, energetic treatment of conjunctival infection, and avoidance of excessive fatigue, excitement, or nervous tension. These measures are simply protective and do not alter the course of the exophthalmos. Treatment of exophthalmos with desiccated thyroid, triiodothyronine, cortisone, estrogens, pituitary, or orbital radiation has given such inconsistent results as to cast serious doubt on their value. If the course of the exophthalmos is steadily progressive and the degree of proptosis is such as to jeopardize the eyes, orbital decompression by surgery is indicated without delay.

Answer.—The bulk of accumulated evidence points to toxic diffuse goiter as being a thyrohypophysial syndrome, and there is much evidence to indicate that the pituitary gland is intimately connected with exophthalmos in this condition, although it is frequently dissociated from the size of the goiter or the degree of thyroid activity measurable.

Exophthalmos may appear before the occurrence of hyperthyroidism or in instances in which it is never detected. It frequently comes during increasing hyperthyroidism and not infrequently appears after its disappearance. It is thought to be due to hyperpituitarism associated with an excess ouput of thyroid-stimulating hormone or a closely connected factor, an exophthalmos-producing substance.

The types of treatment available include the following, most of which are designed to inhibit pituitary activity. It is considered good practice to correct hypothyroidism, and it is probably good practice to correct hypometabolism even though definite evidence of hypothyroidism is not present. The use of larger than physiological doses of desiccated thyroid or triiodothyronine have been tried in the past, with only mild success, but there are now a few instances on record in which prompt and marked improvement has followed the use of large doses of triiodothyronine.

Estrogens and androgens have been used as pituitary inhibitors, but in exophthalmos they have been of little or no practical value. Some patients in this country and in England have been treated with corticotropin (ACTH), cortisone, or hydrocortisone or with combinations of these. Records to date indicate that the response to these substances is not readily practicable. Though dramatic response may occur, the improvement may in some instances be great in the actual proptosis, but in most instances, as more results accumulated, the result is chiefly on soft-tissue swelling of lids and conjunctiva. In those instances in which corneal drying or beginning ulceration threatens, or the loss of an eye, orbital decompression (Nafziger's operation) may be necessary.

The method which has recently been highly successful in a few instances was reported first in 1942, namely, the production of hypopituitarism. A similar patient has recently been reported in the *Journal of Clinical Endocrinology and Metabolism* by M. Albeaux Fernet and co-workers, and other unpublished data indicate that hypopituitarism caused by surgery may be followed by almost complete disappearance of all eye signs associated with severe exophthalmos.

Local eye care and local operations may be useful. One of the most important points is to prevent dryness of the cornea. This can be helped by use of protective ointments at night and the wearing of shields over the eyes to maintain a moist atmosphere over the cornea. Skin divers' goggles are useful for this purpose. If the condition is fairly marked and stationary, covering of the eye may be assisted by tarsorrhaphy. For the associated diplopia, muscle surgery has some usefulness. It has to be postponed until the condition is stationary, and its usefulness is limited because of the type of change which has occurred within the affected muscle, rendering it relatively paralytic due to infiltration of leukocytes, mucopolysaccharides, and later with much associated fibrosis.

OCULAR EFFECTS OF ALCOHOL

To the Editor.—*It has been said that diminution of the visual field is among the first manifestations of physiological disturbances caused by alcohol in drivers of motor cars. Is the fact really proved, or, on the contrary, is it scientifically denied?*

H. Hinglais, M.D., Paris, France.

This inquiry has been referred to two consultants, whose respective replies follow.—Ed.

Answer.—The classic eye sign of alcohol intoxication is the cecocentral scotoma characteristic of tobacco alcohol amblyopia. There is some question whether the scotoma results from alcohol alone. No available text describes contriction of the visual field as an early manifestation of physiological disturbance caused by alcohol. Loss of visual acuity in tobacco alcohol amblyopia is temporary and is recovered shortly after the use of tobacco is discontinued even though the use of alcohol is continued. Diminution in visual acuity occurs with optic neuritis and optic atrophy in methyl alcohol poisoning and may go into total permanent blindness. The first ocular manifestation of alcohol intoxication is diplopia and loss of judgment of distance. This disturbance is of more importance to drivers of motor cars than diminution of vision or constriction of the visual field.

Answer.—It is generally assumed that the effect of alcohol on the central nervous system is due to poisoning of tissue cells so that they are unable to use oxygen properly. In other words, a state analogous to tissue anoxia is produced and would explain the striking effects of alcohol on the central nervous system, since nervous tissue is very susceptible to oxygen want. The symptoms of anoxia in relation to vision are diminished visual acuity, constriction of the visual fields, reduction in retinal sensitivity, and increased fatiguability of the muscles of accommodation and convergence (Wilmer and Berens. *J. A. M. A.* 71:1394-1398 [Oct. 26] 1918). A progressive loss in the visual fields with increasing lack of oxygen has also been reported by Evans and McFarland (*Am. J. Ophth.* 21:968, 1938).

In studying the relationship of alcoholic intoxication and anoxemia, it has been shown that an excess of oxygen and carbon dioxide tended to sober up the subjects more rapidly and that they did better in psychological tests (McFarland and Barach *Am J M Sc* 192 186, 1936)

STEROID THERAPY AND SURGERY

To the Editor —*Recently several articles have stated that, if a patient has had a course of steroid therapy and then has required a major surgical procedure even up to six months after the last dose of cortisone, he should be fortified with cortisone prior to and after the operation Does this apply to corticotropin (ACTH) as well as cortisone and its derivatives? Just what is meant by having had cortisone therapy within six months of the surgical procedure? Does it mean at least one day or one week of steroid therapy? Does the amount of steroid given bear a lot of weight?*

Sidney W Berezin, M D , Spring Valley, N Y

Answer —To date there are no available reports which indicate that the same prophylaxis must be taken with corticotropin as with cortisone However, this should not be considered as conclusive until more time has elapsed

If the patient has had any cortisone therapy within six months of the time of surgery, he should be fortified with cortisone Although this is still questionable, present thinking is that it is a safe prophylactic measure The amount of steroid necessary to produce a depression in adrenal function is still not known, since reactions differ in individuals The amount of steroid given, however, should constitute a guide by which one may determine the amount of fortification necessary

TOXICITY OF PHOTOGRAPHIC CHEMICALS

To the Editor —*Have any toxic symptoms been noted in patients who work with any of the following substances Elon, hydroquinone, Kodalk, potassium alum, potassium bromide, sodium carbonate, and sodium sulfite? Is there any special reference to anemia or bone-marrow depression?*

Morton I Silverman, M D , Allentown, Pa

Answer —The substances mentioned are commonly found in black-and-white photographic developers There is no evidence of anemia or bone marrow depression either in workers who manufacture or package the substances or in photographers who use them as developers The only known toxic symptom is that of occasional contact dermatitis, which may result from continued contact with the alkaline developing solution or occasionally from a specific sensitivity Accidental or suicidal ingestion of large amounts of mixtures of the solid developing agents has been known to give rise to acute hemolytic effects and symptoms resembling those of phenol intoxication On the other hand, hydroquinone has been ingested in amounts as large as 300 to 500 mg per day for several months without any effect on the blood picture in humans (Carlson and Brewer *Proc Soc Exper Biol & Med* 84 684, 1953)

DIAGNOSIS AND TREATMENT OF PERNICIOUS ANEMIA

To the Editor —*Regarding the query entitled 'Diagnosis and Treatment of Pernicious Anemia' in* The Journal, *May 11, 1957, page 221, I notice that the inquirer requests an estimate of the number of patients who may have been treated for pernicious anemia, especially in rural districts, who have never been given a gastric test I can contribute one such case, for I live in a rural area*

Laboratory tests on a patient showed that he had a hemoglobin level below 7 Gm per 100 cc , negative fecal occult blood, and suggestive pernicious anemia There was a reduced vibration sensation of the feet and a history of "thin blood several years previously with associated weakness Inasmuch as free hydrochloric acid was found in the gastric secretion after the histamine test, the case of this patient was apparently one of the rare instances in which pernicious anemia has existed with free hydrochloric acid in the stomach The hemoglobin level was raised to more than 12 Gm per 100 cc through no other therapy than parenterally administered vitamin B_{12} The patient also had a striking improvement in the vibration sensation of the feet During this period he ingested no more liver than would occasionally be included in his ordinary diet

P Evans Adams, M D , Norlina, N C

The above comment was referred to the consultant who answered the original query, and his reply follows —Ed

To the Editor —*There certainly are few patients with pernicious anemia who have free hydrochloric acid but not enough intrinsic factor in their gastric juice to insure adequate absorption of vitamin B_{12} from the gastrointestinal tract This consultant, however, has seen two such patients Moreover, about 35 to 50 such patients have been described in the literature, but not all of these have been thoroughly studied The patient described by the physician writing the comment may well represent another example There are only a few other situations in which improvement following injections of vitamin B_{12} would have been so dramatic On the other hand, the condition is so rare that it is quite justifiable to regard the presence of free hydrochloric acid in the gastric secretion as ordinarily ruling out a diagnosis of pernicious anemia One formerly could prove the absence of intrinsic factor only by collecting the gastric juice and assaying it for intrinsic factor Now one can give a standard dose of radioactive vitamin B_{12} and demonstrate that it is absorbed poorly unless a source of intrinsic factor is administered along with the radioactive B_{12}*

One cautionary comment, however, should be made Vitamin B_{12}-responsive megaloblastic anemia may occur in association with certain diseases or abnormalities of the intestinal tract In these conditions free hydrochloric acid is often present in the gastric contents That is true of idiopathic steatorrhea or nontropical sprue The absence of diarrhea does not exclude this possibility, and the anemia may respond to vitamin B_{12} as well as to folic acid

The megaloblastic anemia due to fish-tapeworm or Ascaris infestation will be corrected by the administration of vitamin B_{12}, *free hydrochloric acid is occasionally found in the gastric juice One may rarely see a strict vegetarian who has a dietary deficiency of vitamin* B_{12} *The megaloblastic anemia seen with intestinal strictures, anastomoses, or massive diverticula of the small intestine usually responds better to folic acid but may at times show improvement after therapy with parenterally administered vitamin* B_{12} *The fact that the patient described in the comment above responded to injections of vitamin* B_{12}, *therefore, indicates that he probably had a vitamin* B_{12} *deficiency, but it does not necessarily prove that he has true pernicious anemia Additional studies would be necessary to provide that evidence For a report of such an investigation see the article by Harris-Jones and associates (*Blood 12 461, *1957)*

WESTERGREN SEDIMENTATION RATE TECHNIQUE

To the Editor —*In the Queries and Minor Notes section of* The Journal *for May 25, 1957, page 509, there is a comment regarding the correct normals for the Westergren method of determining the sedimentation rate of erythrocytes*

*Clay-Adams, Inc, manufacturer of laboratory supplies, had occasion in 1956 to recheck its standards and literature on this subject After extensive investigations and consultations with several hematologists, it was decided that our old instructions were incorrect insofar as normals were concerned, and these were changed to agree with the limits of sedimentation rate advocated by Westergren Westergren gives a normal range of 1 to 3 mm sedimentation after one hour for men and 4 to 7 mm sedimentation after one hour for women (*Acta med scandinav 139 214, *1951) Ham gives the same normal range limits which are based on a dilution rate of 1 part of sodium citrate (3 8% solution) to 4 parts of blood Where the dilution rate is reduced to 1 part of sodium citrate solution to 8 or 9 parts of blood, the normal sedimentation rate is given as 0 to 15 mm after one hour for men and 0 to 20 mm after one hour for women (Todd and Sanford Clinical Diagnosis by Laboratory Methods, Philadelphia, W B Saunders Company, 1948)*

Gradwohl appears to be incorrect He suggests a dilution of 0 4 cc of sodium citrate solution to 1 6 cc of blood, or 1 to 4, then gives the normals for a dilution rate of 1 to 8 (Gradwohl Clinical Laboratory Methods and Diagnosis, ed 5, St Louis, C V Mosby Company, 1956, vol 1, p 961)

Helpful references to this same question appeared in the Queries and Minor Notes section of The Journal *for March 23, 1940, page 1101, and again for Dec 3, 1955, page 1422*

CONSTANT PERSPIRATION OF THE HANDS

To the Editor — *In* The Journal, *June 29, 1957, page 1040, I notice the answer to the query entitled "Constant Perspiration of the Hands" This condition of hyperhidrosis can be completely disabling for certain individuals, and when the condition cannot be controlled with conservative medical measures, the operation of thoracic sympathectomy is indicated This operation has been performed for many years for hyperhidrosis involving the upper extremities The operation of bilateral second thoracic ganglionectomy can also be performed with little risk, this does not produce bilateral Horner's syndrome, which will be produced if a stellate ganglionectomy is performed*

J Grafton Love, M D
Mayo Clinic
Rochester, Minn

The above comment was referred to the consultant who answered the original query, and his reply follows —Ed

To the Editor —*Few cases of hyperhidrosis of the hands are so severe and so resistant to conservative management as to make sympathectomy necessary While this procedure is successful in drying the hands, dermatologists see more trouble from dry skin than from hyperhidrosis It is necessary to open the chest bilaterally to perform this operation, and there are possible complications Most local neuro surgeons require from two to three hours for the procedure, it may be necessary to do it in two stages This is a major procedure for a minor condition Many question the advisability of performing major surgery for a psychosomatic manifestation Certainly, sympathectomy should be reserved as a last resort in the treatment of hyperhidrosis of the hands*

CANDIDA OVERGROWTH FOLLOWING ANTIBIOTIC THERAPY

To the Editor —*The reply of the second consultant to the query regarding pruritus following Terramycin therapy in* The Journal, *June 22, 1957, page 940, was very erudite, but the ointment recommended would be very expensive The San Diego price for 10 Gm of prednisone to be added to the salve advised would be about $100 Could there have possibly been a misprint in the recommended dosage?*

James E Reeves, M D
205 Walnut Ave
San Diego 3, Calif

The above comment was referred to the consultant who answered the original query, and his reply follows —Ed

To the Editor —*The addition of 10 Gm of prednisone (Meticorten) was an obvious error What was meant was 10 Gm of 0 5% prednisolone cream (Meti-Derm) or 5 Gm of 2 5% hydrocortisone acetate with neomycin sulfate (Neo-Cortef) or a similar hydrocortisone like product to yield 34 Gm of salve*

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, MAY-AUGUST 1957

Abstracts have been made of important articles in the following journals in the Current Medical Literature Department of THE JOURNAL during the past four months Any of the journals, except those starred will be lent by the Library of the American Medical Association to individuals in Continental United States and Canada who subscribe to its scientific periodicals and to members of the American Medical Association and its student organization No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each periodical Three journals may be borrowed at a time for a period not exceeding five days Thus most of these journals are accessible to the general practitioner

STOKES Adams Syndrome See Heart block
STOMACH
achlorhydria in diagnosis of pernicious anemia 221
achylia in old age partial megaloblastic erythropoiesis and slight anemia with [Pedersen] 334—ab
acid secretion caffeine effect on 508
acidity and pepsin studies in Curling s ulcer [Hummel & others] *141
acidity free acid without atrophy in pernicious anemia [Harris Jones] 1614 ab
acidity tests in patients treated for pernicious anemia how many given? 221 (replies) [Adams and original consultant] 2101
acidity tubeless analysis [Bolt] 97—ab
acidity tubeless method with azure A resin compound vs intubation with histamine to determine [Rechtschaffen & others] *1406
biopsy to study non ulcer dyspepsia [Williams] 343—ab
cancer gastrectomy for, late results [Binda] 1617—ab
cancer of antrum surgery for [Tabb] 1719—ab
digestion of homogenized milk in school children [Czech] 1398—ab
dilatation functional treatment 357
emptying rate United Kingdom 911
function in ulcer treated medically [Olesen] 1971—ab
gastroesophageal sphincter United Kingdom 911
gastroscopic accidents [Palmer & Wirts] *2012
gastroscopic appearance after surgery [Friedrich] 924—ab
hemorrhage massive from reserpine [St James] 1711—ab
hemorrhages severe [Vandenbroucke] 99—ab
inflammation (erosive gastritis) in cirrhosis [Palmer] 330—ab
mucosa duplication of cystic and common hepatic ducts lined with [Lee] 1075—ab
mucosa lipase activity under pathological conditions [Siurala] 1167—ab
secretion and psychological characteristics relation in etiology of duodenal ulcer [Weiner] 208—ab
Surgery See also Peptic Ulcer and other subheads under Stomach
surgery Billroth I resection [Horsley] 1713—ab
surgery deltacortisone for postgastrectomy deficiency edemas [Vesin] 603—ab
surgery gastrectomy orthostatic hypotension after [Cohen] 1978—ab
surgery glucose tolerance after 1858
tumors neurinomas chemical aspects [Pelper] 1977—ab
Ulcer See Peptic Ulcer
varices bleeding portacaval anastomosis in United Kingdom 322
STOMACH TUBE
gavage of patients after laryngectomy [Pescetti] 1309—ab
STOVE
liquid gas danger control and dosage of carbon monoxide [Ricci] 1034—ab
STRABISMUS
isoflurophate in N N D 875
STRAIN
tenosynovitis due to in Jai Alai players treatment 1171
STREPTOCOCCUS
infections erythromycin for [Romansky & others] *1197
STREPTOLYSIN See Antistreptolysin
STREPTOMYCIN
anaphylactic response to incidence 945
treatment plus chloramphenicol for septic arthritis after steroids [Mills & others] *1310
vs isoniazid for tuberculous meningitis in children [Ratner] 215—ab
STRESS
exhaustion and (Council article) [Bortz] *2059
STRIDOR
pediatric bronchography in diagnosis [Ferguson & Flake] *518
STRIKES
doctors Sweden 909
STROKES See Brain hemorrhage
STRONGYLOIDIASIS
Brazil 1498
STRONTIUM
radioactive for cancer (guest editorial) [Garland & Heald] 1097—E (correction) 1943
STRUMA
Lymphomatosa (Hashimoto s Disease) See Thyroid
ovarii aberrant thyroid tissue [Dalgaard] 109—ab
STUDENTS
college immunization against diphtheria [Boynton & others] *1874
science visit health institutes 1364

loan fund (Temple U) 192 (U of Pennsylvania) 587 (U of Texas) 803 (in New Jersey) 1260
orienting toward whole patient [Whitehorn] *538
plethora of Argentina 481
second year at U of South Dakota examine patients 409
sex education for United Kingdom 1009
SUBDURAL See Meninges
SUICIDE
among middle aged men Denmark 82
attempted gamble with death in [Weiss] 817—ab
attempted with tranquilizers United Kingdom 1962
brain injury and [Sperling] 928—ab
during economic prosperity incidence 1293
poisoning fatalities United Kingdom 795
problem in corundum furnace tender [Adebahr] 1165—ab
problem of and weather conditions [Im Obersteg] 1395—ab
thoughts of in manic depressive disease [Cassidy & others] *153
SULFISOMIDINE
N N D 2018
SULFOBROMOPHTHALEIN
excretion test method 829
SULFONAMIDES
bacterial resistance and hospital infection [Koller] 929—ab
to prevent rheumatic fever relapses France 1409
treatment for complications of measles United Kingdom 321
SULFONIAZID
antituberculous activity France 84
SULFONYLUREAS (carbutamide tolbutamide)
Argentina 1951
carbutamide effect on blood lipids in diabetes [Corsini] 1817—ab
experimental study of BZ 55 [Connard] 1985—ab
hypoglycemic response to insulin after [Mirsky] 1015—ab
hypoglycemic vs antidiabetic action of tolbutamide 562 E (reply) [Collens] 1812—C
oral insulin substitute [Duncan] 1851—ab
polyneuritis from carbutamide Netherlands 1115
tolbutamide for diabetes 562—E [Breneman] *627 (reply) [Felder] 1801—C
tolbutamide for diabetes American Diabetes Association statement on (Miscellany) [Colwell & others] *1151
tolbutamide for diabetes N N D 1333
treatment of diabetes [Ricketts] 209—ab [Brednow] 216—ab
treatment of tuberculous diabetics hepatic function in [Pulsetti] 1506—ab
SULFUR
radioactive behavior after external application to skin [Scott] 931—ab
SULPHONES See 4 4 Diaminodiphenyl Sulphone
SUMMER
medical aspects of vacation 1336—E
Summer Round Up grows up PTA program A M A cooperation (guest editorial) [Helmholz] 52—E 66
SUNLIGHT
as cause of melanoma [Lancaster] 1518—ab
SUPERSONICS See Ultrasonics
SUPPOSITORIES
aminophylline contraindicated in girl 10? 1629
SUPRARENALS See Adrenals
SURFACAINE See Cyclomethycaine Sulfate
SURGEONS
doctor or mister? United Kingdom 322
radiodermatitis in [Dufourmentel] 1390—ab
SURGERY
after corticosteroid or ACTH treatment preoperative steroid fortification 2101
blood 17 hydroxycorticosteroid changes during [Vilkari] 1612—ab
building at San Diego Naval Hospital (photo) 1135
cancer cell seeding of wounds causes failure in cancer treatment [Smith] 2092—ab
cholangiography during practical value [Wall & Peartree] *236
complications after operations for esophageal atresia [Urban] 492—ab
electric in breast cancer [Carranza] 810—ab
for sciatica Finland 595
general anesthesia with hypothermia in [Leger] 1406—ab
SURGERY—Continued
general fatal postoperative pulmonary complications in [Becker] 1977—ab
general pediatric hypothermia in [Brayton] 700—ab
general vascular emergencies in [Bruckschwaiger] 1278—ab
